

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

A

Aachen treatment of syphilis, 1205
 Aschoff, Dr. L., honorary degree, 625
 Aaron, Dr. S. J., medical treatment of uterine hæmorrhage, 1352
 Abattoir, public, for London, 516
 Abderhalden, H., Manual of Physiological Chemistry (review), 796
 "Abdomen, the acute," (Annus Medicus, 1786)
 Abdomen, two unique congenital deformities in the, of same patient, 440
 Abdomen, congenital abnormalities in the, 454
 Abdominal Aorta, aneurysm of the (Dr. F. P. Nunneley) (review), 1078
 Abdominal aorta, embolism and thrombosis of the, the result of mitral stenosis and consecutive cardiac thrombosis, gangrene of both feet and legs due to (Dr. H. W. Syers), 220
 Abdominal atony in rickets, 878
 Abdominal hysterectomy for fibroid under spinal analgesia, 1729
 Abdominal lymphatic glands and stomach, sarcoma of, 1684
 Abdominal operations, cause of fatal collapse after prolonged, 1789
 Abdominal pregnancy, case of wrongly diagnosed, 285
 Abdominal route, value of the, in operations for uterine cancer, 130
 Abdominal section, general management of cases of, 1514
 Abdul Hamid, enlarged prostate, 529
 Aberayron, no water-supply and no-drainage, 1475
 Aberdeen Eye Institution, 911
 Aberdeen University, Anatomical and Anthropological Society, 52
 Aberdeen University quatercentenary, 194, 823, 943, 1012; and President of General Medical Council, 1558; honours to Italian men of science at the, 964; the Vatican and, 836
 Aberdeen, Lunacy Board, 194; public health committee, 184; proposed sanatorium for, 1693

Aberdeen University Club, London, 1289
 Aberystow, typhoid fever in, 1475
 Aberystwyth Board of Guardians, 1383
 Abnormalities, congenital, in the abdomen, 440, 454
 Abnormality, congenital, of the genito-urinary organs, a case of (Mr. G. F. D. Smith and Mr. A. L. H. Smith), 156
 Abolition of capital punishment, 1295
 Abolition of imprisonment for contravention of by-laws, 1246
 Abolition of quarantine for Mecca pilgrims, 1252
 Abortifacients and quacks, 248
 Abortion feloniously induced by diachylon, 387, 1681 (Annus Medicus, 1794)
 Abortivists, convictions of, 1485, 1745; recent prosecutions of, 1613
 Abortions, repeated, and ventro-suspension, 1594
 Abram, Dr. J. H., gastric ulcer and dyspepsia, 1217
 Abrams, Dr. Albert, amyl nitrite in hemoptysis, 1686
 Abscess, appendix, with an unusual complication, case of (Mr. Russell J. Howard), 160
 Abscess, hepatic, two cases of, treated by the transpleural operation (Surgeon-Captain H. Taylor), 856 (Annus Medicus, 1785)
 Abscess in right cerebral hemisphere, 1515; of lung, 1446; splenic, in malarial fever, 1159; trephining for intracranial, 1443; tuberculous, treatment of, 878
 Abscess, perineal, flagellated protozoa in a (Dr. E. H. Hunt), 218
 Abscess, primary, of the left lung exhibiting spontaneous cure; metastatic manifestation in the pelvis declaring itself after a year's latency with abscess formation and slow spontaneous cure. A case of actinomycosis (Dr. Edgar Trevithick), 158
 Abscesses, pharyngeal (Dr. George E. Waugh), 845
 Abuse (see Hospital abuse)
 Academy of Medicine, Paris, 195
 Accessory sinuses of the nose, study of anatomy of, 875; skiagraphy in diagnosis and treatment of diseases of, 875

Accident and Injury, Diseases of the Nervous System Resulting from (Dr. Pearce Bailey) (review), 1595
 Accident to the Plymouth boat express, 179
 Accident mitigation in America, 821
 Accidents, due to chloroform inhalation, 1232; due to petroleum l-mps, 1379; provision for, on race courses, 452; to jockeys, 452
 Accidental burning or overlying mortality of children from, 143, 749, 980
 Accommodation and motility, dependence of, upon the refraction, 811
 Acetone, a new microbe producing: bacillus violarius acetonicus, 452
 Acetone collodion, 908
 Acetonuria and delayed chloroform poisoning, 1752
 Acetonuria, acute, and anaesthesia, 1643
 Acetozone, intestinal antiseptic, 1583
 Acetozone, treatment of iritis, interstitial keratitis, by, 679
 Acetylene and gas-stoves, 1363
 Acetysal, 1391
 Acidity, gastric, improved clinical method for estimation of factors of, 1730
 Acidity of urine, new method for determining, and clinical value of the results, 1381, 1683
 Ackery, Mr. John (obituary), 1768
 Acland Home, Oxford, 1069
 Acland, Dr. T. D., Cairo medical school, 1741
 Acomb, Mr. L. H., note on a case of upward and backward dislocation of the clavicle, 524
 Acromegaly, case of, 1216
 Act (see Adoption of Children, New Zealand, Apotheecaries, Commerce of Australia, Contagious Diseases (Animals), Coroners (1887), Coroners and Deaths Registration, Employers' Liability, Factory, Housing of Working Classes, Inebriates, Infectious Diseases (Notification), (Prevention), Lunacy, Medical of Victoria, Medicine Stamp Duty, Merchandise Marks (1887), Midwives, Oaths, Pharmacy (1868), Public Health, Pure Food of Victoria, Sale of Food and Drugs, Spirits, Trade Marks and Patent, Vaccination, Workmen's Compensation)
 "Actojner," a curious name, 1566

- Actinomycosis**, a case of; primary abscess of the left lung exhibiting spontaneous cure; metastatic metastation in the pelvis declaring itself after a year's latency with abscess formation and slow spontaneous cure (Dr. Edgar Trevithick), 158
- Actinomycosis of the neck** cured by iodide of potassium (Dr. R. Knox), 1213; and bakers in Austria, 471; case of, 1307; of the vermiform appendix, 996; suggested infection by tainted food, 1214
- Actions against medical men by their patients** and *vice versa*, 39
- Actions at law** against a medical man for alleged communication of scarlet fever to a female patient, 250; against a medical man for alleged manslaughter, 42, 237; against a medical man for alleged negligence, 1301; against a medical man for assault on a girl of six, 47; against dentists for alleged negligence, 1033, 1555; against a herbalist for practicing as an apothecary, 58; against a man for injury from handshakes, 1321; against proprietor of Tallerman Bath establishment for burns, 267; against two medical men for alleged malpractice, 1618; against a medical man for typhoid contracted at a hydro, 1745 (*Annus Medicus*, 1792)
- Acute obstruction of the intestine**, case of appendicitis complicated with, 1070
- Acute yellow atrophy of the liver**, 995; presumed case of, 936
- Adami, Prof. J. G.**, arterio-sclerosis, 870; glioma and tuberculosis, 869; the part played by the nucleus in nutrition, 737
- Adamkiewicz, Prof. A.**, cancerine, 1412
- Adams v. Clarke and another**—Clarke cited, 1682
- Adams, Mr. C. E.**, unfounded reflections upon, 949
- Adams, Mr. J.**, gonorrhœa, 1445
- Adams, Dr. J. A.**, spasm of muscles of lower part of trunk and thigh, 1072
- Adamson, Dr. H. G.**, lichen spinulosus, 1074
- Adcock, Mr. G. R.**, trial of, 42; and death of Major Whyte (leading article), 237
- Addenbrooke, Dr. B.**, note on two cases of scleroma neonatorum occurring in twins, 236
- Addison's disease**, blood pressure and pigmentation in (Dr. A. Rendle Short), 235
- Addison's disease**, 1355
- Adnomas of the labium**, 162
- Adhesiva peritonitis**, 129
- Adler, Mr. J. Birck**, a radium applicator, 1598
- Admiralty and physical training**, 188
- Adolescent or late rickets** (Mr. H. H. Clutton), 1070, 1288
- Adoption of Children Act, New Zealand**, amendment of, 118
- Adrenalin**, 352
- Advertisement** (see Sale of Food and Drugs Act, Brandy, Butter)
- Advertisement**, a rather ambiguous, 276
- Advertisements and circulars**, 969; disgusting, 842; in public urinals, 204; misleading, 1630
- Advertising and dentistry**, 1006, 1169
- Advice given refused**, 1163
- Advocacy**, unfortunate, 1321
- Aero-traffic**, 1674
- Aischylus** (translated by Lewis Campbell) (review), 1731
- Aerzte Verein Verband** (Union of Medical Societies), Vienna, and club appointments, 1313
- "Affenpauke"** in gorilla's brains and in human brains, 1314
- Africa** (see Congo, South Africa)
- African arrow poison**, physiological action of a recently discovered, 687
- African, South, civil surgeons**, 124
- After-care Association**, 1784
- Age**, old (see Centenarians, De Senectute, Senile, Longevity)
- Agency routine**, deputation in, 907, 970
- Agglutination of vibrios**, further observations on the influence of calcium chloride on the (M. Crenidropoulos and Dr. Amos), 1722
- Agosticism and Determinism**, 431
- Agoraphobia**—a remedy (Dr. Charles Mercier), 930
- Agramonte, Dr. A.**, yellow fever, 1221
- Agriculture and Fisheries**, Board of, Annual Report of Veterinary Department of, for year 1905 (review), 166; horticultural exhibition, 1347; useful publication by, 176; and vivisection, 751
- Agriculture**, Department of, Belfast, 262
- Agricultural research**, promotion of, 245
- Agriculture**, United States Department of, and THE LANCET, 109
- Ainhum**, case of (Dr. D. M. Alexander and Dr. R. Donaldson), 858
- Air, compressed**, hardening of steel by a current of, 457
- Air, embolism of**, unique case of, with embolism of telegic material, 366
- Air, fresh**, and influenza, 1828
- Air, injection of**, evacuation of a large chronic pleural effusion by, 1296
- Air of the subways**, condition of the (New York), 131
- Air-borne infection**, 1224
- Air-supply of the House of Commons**, 449
- Aix-les-Bains**, source of deux reins, 1106
- "Albany" gas stove**, 1261
- Albumin**, egg, case of hydrosynera to, 256
- Albuminuria**, functional, in athletes, 1563
- Albuminuria**, hemogenous (Dr. E. Hingston Fox), 497, 514, 680, 761
- Albuminuria in late lactata**, 1071
- Albumosis**, from bacillus enteritidis sporogence, 1223; in rectal alimentation, 1261
- Alcock, Dr. N. H.**, theory and practice of medical education, 921
- Alcohol**, and the diet of sailors, 1173; compressed in treatment of intestinal perforation, 1382; consumption of, and tobacco in Canada, 1179; death from rum, 1311; effects of in hospital and asylum practice, 69; estimated to give 90 percent of body heat, 1300; in disease, 997; in France, 1331; injections of, in nervous affections, 822; in insanity, 702; in rectal alimentation, 1266; is it normally present in the blood and tissues? 1299
- Alcoholic fluids**, the use of, 666, 970
- Alcoholic poisoning**, death from, 1485
- Alcoholic subjects**, pneumonia in, 954
- Alcoholism**, a Chapter in Social Pathology (Dr. W. C. Sullivan) (review), 1730
- Alcoholism**, increase of, amongst women in Austria, 1178
- Alcoholism in France**, 528
- Alcoholism**, the struggle against, 1756
- Alden, Mr.**, meat inspection, 1563; medical relief and starvation cases, 1319, 1409; relief of sickness in Whitechapel, 1563
- Aldous, Mr. G. F.**, psychology of the selfish motorist, 896
- Alexander, Dr. D.**, arrow poison, 667
- Alexander, Dr. D. M.**, case of ainhum, 858
- Alexander, Mr. F. W.**, standardisation of disinfectants, 123; determination of sex by electrical influences, 322; electrolytic disinfectant, 453; electrolysed salt solution, 1457
- Alexander, Dr. J. F.**, case of fracture of the sternum, 636
- Alge**, prevention of growth of, in open reservoirs, 180
- Alhambra**, "thought reading" at the, 1259
- Aliss**, a medical, 1109
- Alimentary canal**, and longevity, 1333; and streptococci, 1418
- Alimentary hygiene**, International congress of, Paris, 835, 1313
- Alimentation**, rectal, the Bradshaw lecture on (Dr. Seymour J. Sharkey), 1263 (see also Rectal Alimentation)
- Alkali trades and factories and workshops**, extensions of the provisions in regard to the control of, 1011
- Alkaline picric acid test** for sugar, 1140
- Alkaptonuria**, case of, 1216
- Allan, Mr. H. W.**, presentation to, 1628
- Allan, Dr. J.**, coexistence of diseases, 679
- Allan, Mr. J.**, thoracotomy for traumatic hemothorax due to a wound of an intercostal artery, 855
- Allan, Dr. J. W.**, need for a progressive study of industrial diseases, 1218
- Allbutt, Prof. T. Clifford**, an address on words and things, 1120; a System of Gynecology by Many Writers (review), 94; arterio-sclerosis, 870; honorary degree, 625; hygiene in elementary schools, 1394; "prodromata," 1304; the relation of blood pressure to arterial sclerosis, 728
- Allen and Hanbury, Messrs.**, fire in Bethnal Green works, 1110; preparation of infants' food, 204
- Alnwick, Mr. William Williams**, 1301
- Alopecia areata**, recurrent attacks of, 1444
- Alvarang's prizes** of the College of Physicians of Philadelphia, 1297
- Allypine and novocaine**, comparison with cocaine, 1614
- Amalgamation of London medical societies**, 240, 1381, 1469, 1512, 1562
- Amalgamation**, proposed, of medical societies in Victoria, 1855
- Amalgamation scheme**, City Orthopaedic Hospital, 133
- Amanita phalloides**, consideration of the poisons present in, 738
- Amann, J. A.**, Die Krankheiten des Beckenbindegewebes: The Diseases of the Pelvic Connective Tissue (review), 1219
- Amara**, in infants, 767
- Amazon**, first report of the expedition to the, 1905, 668
- Amblyopia** (*Annus Medicus*), 1732
- Amblyopia in young children**, on a form of, consequent upon inherited syphilis (Mr. S. Stephenson), 357
- Amblyopia, tobacco** (Mr. Percy Dunn), 1491
- Amblyopia and ptoxis** in an infant, 358
- Ambulance**, automobile, for city of London, 1542; carriage for Belfast, 962; horsed, 1294; motor, for Belfast, 466; motor wagon, St. Andrew's, 951; street, service for London, 39, 121, 201, 321, 1299, 1542, 1635, 1750; spring, the "Rashion," 236
- Ambulance**, volunteer school of instruction, 1026, 1621, 1748
- Ambulance Association**, Metropolitan Street, 39, 121, 201, 321, 1294, 1542, 1635, 1750; St. Andrew's, 193
- Ameorrhœa and chlorosis**, 1427
- America** (see also New York)
- America**, accident litigation in, 821; plague in (*Annus Medicus*), 1809
- American**, food of the workman, 1379; a new medical directory, 819; tinned meat, 18; opinion on value of rifle instruction, 1683
- American Mosquito Extermination Society**: Year-book for 1904-1905, containing the proceedings of the second anti-mosquito convention held in New York, December, 1904 (edited by H. C. Weeks and E. H. Hall) (review), 1289
- American Roentgen Ray Society**, annual meeting, 1400
- Amino acids and metabolism**, 730
- Amoeba**, structure and functions of the, 738
- Amebic dysentery**, 1494
- Amos, Dr. C. B. S.**, note on the treatment of catarrhal and gangrenous dysentery, 286; further observations on the influence of calcium chloride on the agglutination of vibrios, 1722
- Ampulla of Vater**, acute hemorrhagic pancreatitis following obstruction of, 1379
- Amputation of the shoulder-girdle**, notes on two cases of (Dr. J. Crawford Benton), 154
- Amputations of the foot**, conservative, 1478
- Amyl nitrite** in hemoptysis and in other hemorrhages: recent results, 1435, 1685, 1830
- Amos, Prof. (Toronto)** lysol and cresoline, 1553
- Anæmia in childhood**, some unusual forms of (Dr. T. M. C. Whipham and Mr. A. N. Leatham), 367
- Anæmia**, hypodermic injections of iron in, 384; in natives at Johannesburg, 718; pseudo-leukæmia infantum, 1147; a form of, in young children, 1677
- Anæsthesia**, after-effect of ethyl chloride, 257; in abnormal and constrained positions, 1287; surgery of central nervous system, 485; mortality under, in Hungary, 964
- Anæsthesia in Dental Surgery** (Mr. T. D. Luke) (review), 658, 760
- Anæsthesia**, local, strangled hernia operated cases of, 1435; medullary, series of 1000 cases of, 472; spinal, in surgery, 1160; with novocaine, 1404 (*Annus Medicus*), 1802
- Anæsthetic**, new method of administering, through a tracheotomy tube (Dr. Walter F. Cooke), 717
- Anæsthetic** (see "Anæsthesia," Beta-eucaine, Ethyl bomidie, Ethyl chloride, Ethyl iodide, Novocaine, Phenol, Somnifera, Stovaine, Suprarenal extract, Allypine, Cocaine)
- Anæsthetic apparatus**, 952
- Anæsthetics** (review of in *Annus Medicus*), 1800
- Anæsthetics for dental operations**, precautions, 1298; in ocular therapeutics, 14
- Anæsthetists**, Society of, annual dinner, 1185; meeting of, 1287
- "Anæsthesia"**, 1435
- Analgesia** (see Anæsthesia)
- Analgesics in ocular therapeutics**, 15
- Analysis**, Methods of Organic (Mr. H. C. Sherman) (review), 658
- Analysis of canned meat**, Ottawa, 1180; suspected food-stuffs, 523; of tinned meat, Wiltshire, 436; of the water from the holy well of Zem Zem, 450
- ANALYTICAL RECORDS FROM THE LANCET LABORATORY**—Vasiment; (1) Red Voslauer Goldeck; and (2) Red Voslauer Goldeck Cabinet; Hommel's Hamatogen (Free from Alcohol); Graminol; Axe Vale Cider; Artex Food; (1) Seitzo; and (2) Kentoph; Grape Port; Grape Juice, 303, 304—(1) Tabloid Laxative Fruit Pastille; (2) Tabloid Menthon and Eucalyptus Pastille; and (3) Tabloid Menthon Pastille; The "M. D." Disinfectant Cream; The Dorotia Cigarette; Cape Colony Mineral Water; Pure Toffee; Diastase Cocoa; Reid's Stout; 799—Pancreon; Papkerchets; Antifly Pepper; Cream of Tartar; Potent Arrowroot; Cyllin Syrup; "Nou-shing Stout"; Hercules Hungarian Mineral Water; Ca-heterpurin; "Tabloid" Hypoc-

- dermic Trinitrin, 1078, 1079—Preparations of Formates, Old Champagne Brandy (1854); (1) Saloid Products for Ophthalmic Use, and (2) Tabloid Xaxa and Dover's Powder; Miel; Swedish Bread (Schumacher); Stypsvival Triburates; Chevalier Malt Flour; Vitalla, 1359
- Anatomical Vocabulary in Four Languages** (Bomenclature Anatomique en Quatre Langues) (Dr. Paul Rodet) (review), 565
- Anatomy**, chair of, in University of Manchester, 1630
- Anatomy**, Edinburgh Stereoscopic Atlas of (Dr. D. Waterston) (review), 444
- Anatomy**, Human, Atlas and Text-book of (Dr. J. Sobotta) (review), 1077
- Anatomy**, Human, Hand-atlas of (Prof. W. Spalteholz) (review), 1001
- Anatomy**, Histology and Embryology, the Frog, an Introduction to (Dr. A. M. Marshall) (review), 1016
- Anatomy**, Manual of, Systematic and Practical, including Hæmatology (Dr. A. M. Buchanan) (review), 1000
- Anatomy**, report of the Select Committee on, 672; study and teaching of, 896
- Anatomy**, Studies in, from the Anatomical Department of the University of Manchester (Mr. A. H. Young) (review), 344
- Anatomy**, Text-book of (edited by Prof. D. J. Cunningham) (review), 28
- Anatomy**, of flowering plants, 506
- Anatomy**, of the human eye, 476
- Antacid and modern soap**, 1258
- Ancient medical MSS.** from Syria, 1157
- Andaman Islands**, sickness in, 267
- Anders, Dr. J. M.**, a Text-book of the Practice of Medicine (review), 882
- Anderson, Dr. (Yale)**, heart disease in athletes, 131
- Anderson, Dr. J.**, tumour involving lung, pleura, and mediastinum, 1072
- Anderson, Dr. J., C.I.E.**, appointment, 1539
- Anderson, Dr. J. W.**, meeting's, 639
- Anderson, Dr. W.**, diploma of membership of Royal College of Surgeons of England burnt, certificate issued, 1360
- Anderson, Major A. R. S.**, splenic abscess in malarial fever, 1159
- Anderson, Mr. W. M. A.**, honour to, 1377
- Anderson-Berry, Dr. D.**, claim that Prof. von Behring held homeopathy's doctrine, 1751
- Anderson's College Medico-Chirurgical Society**, dinner, 1652
- Anderson district, Glasgow**, proposed new dispensary, 1311

Dawson on blood pressure in relation to disease, 728; Dr. G. A. Gibson on clinical methods of investigating the blood pressure, 728; Sir William H. Broadbent on the clinical and therapeutic indications of morbid blood pressure, 728; Prof. T. Clifford Allbutt on the relation of blood pressure to arterial sclerosis, 738; Dr. Alfred Stengel on some clinical manifestations, visceral and general, of arterio-sclerosis, 729; Prof. Russell H. Chittenden on over-nutrition and under-nutrition, with special reference to protein metabolism, 729; Dr. L. F. Barker on amino-acids and metabolism, 730; Dr. W. B. Thistle on the treatment of typhoid fever, 731; Mr. Sinclair White on the surgical treatment of ascites secondary to vascular cirrhosis of the liver, 731; Mr. J. Lynn Thomas on enucleation of the prostate, 732; Dr. G. H. Armstrong on the successful removal of the spleen in a case of Banti's disease, 733; Dr. A. H. Frelund on the relation of gynecology to the work of the general practitioner, 733; Prof. Adam H. Wright on concealed accidental hemorrhage, 733; Dr. W. Gardner and Dr. J. R. Goodall on chronic metritis and arterio-sclerosis of the uterus, 734; Dr. Arthur E. Giles on a study of 146 consecutive cases of ventro-fixation of the uterus, 734; Dr. Charles A. L. Reed on changes in uterine fibroids after the menopause considered with reference to operation, 735; Dr. H. L. Reddy on indications for Cesarean section other than pelvic deformities or tumours, 736; Dr. T. A. Helme on the appendix vermiformis in relation to pelvic inflammation, 737; Prof. Adams on the part played by the nucleus in nutrition, 737; Prof. W. D. Halliburton on proteidomenclature, 738; Dr. De'eszene on tryptic digestion, 738; Dr. S. P. Bebe on nucleo proteid immunity, 738; Dr. Folin on the metabolism of kreatin and kreatinin, 738; Dr. Mendel on chemical and physiological studies on growth, 738; Prof. O. F. Hedge and Prof. M. F. Duncan on structure and functions of the amœba, 738; Dr. R. M. Pearce and Dr. H. O. Jackson concerning the production of somatogenic cytotoxins by the injection of nucleoproteids, 749; Dr. W. W. Ford on a consideration of the poisons present in amanita phalloides, 739; Prof. W. H. Mainwaring on the application of physical chemistry to serum pathology, 739; Prof. E. Muir and Dr. W. B. M. Martin on the combining properties of opoamins of normal serum, 739; Dr. F. J. Smith and Dr. C. Miller on gastric erosions, 739; Dr. G. H. A. Clowes on the etiology and life-history of x malignant new growths, 739; Dr. Samuel Dixon on phthisis prevention, 741; Dr. Gilchrist on certain analogies between influenza and pulmonary tuberculosis, 741; Dr. Probst on the disputed questions in connection with pulmonary tuberculosis, 741; Dr. Honan on the dust problem as shown in public buildings and private houses, 741; Dr. Robison on the protection and filtration of water-supplies, 742; Dr. A. E. Dieffenhard on the etiology of general paralysis, 743; Dr. C. K. Mills on cerebral localisation in the study of psychiatry, 743; Dr. John Turner on the central nervous system of epileptics, 743; Dr. Aldren Turner on epilepsy, 742; Mr. J. B. Laidford on rare forms of choroiditis, 743; Mr. Lawson on the preventive treatment of eye pathetic ophthalmitis, 744;

Dr. Aschoff on the pathological basis of irregularity and failure of the heart muscle, 800; Dr. F. J. Smith on the treatment of typhoid fever, 801; Dr. W. G. Spiller on a case of syringomyelia with a cavity traced from the sacral region to the upper part of the internal capsule, 802; Dr. J. J. Putnam on a comparison of certain modern phlebotomic doctrines with reference to their bearing on the therapeutics of psychasthenia, 802; Dr. S. Flexner on the serum treatment of cerebro-spinal meningitis, 802; Dr. George Dock on paracentesis of the pericardium, its indications and methods, 802; Dr. McCallum on gastro-neurasthenia, 802; Dr. Campbell Meigs on the pre-insane stage of ante-mental disease, 802; Dr. William J. Mayo on the surgical treatment of duodenal ulcer, 802; Mr. C. J. Bond on the treatment of acute septic peritonitis, 803; Prof. H. Harcourt on the milk-supply and disease, 804; Dr. J. J. Cassidy on the hygiene of the home, 805; Miss Helena MacMurchy on the medical inspection of children attending elementary schools, 805; Dr. F. H. Bryce on the medical examination of immigrants, 806; Dr. Jeanie Drennan on State control of health, 806; Mr. MacGill on legislation for food preservatives, 806; Dr. H. M. L. Johnson on the national supervision and standardisation of food, 807; Mr. William Spooner on sailors' foods, 807; Dr. J. M. Atkinson on plaga procedure in Hung-Kong, 807; Dr. Louis S. McMurtry on the surgical and serum treatment of puerperal sepsis, 809; Dr. Ross on the study of 70 cases of ectopic gestation, 809; Prof. Lapteque on electrical stimulation of muscle and nerve, 810; Dr. F. W. Mott on the physiological significance of the convulsional pattern in the brain of primates, 810; Dr. H. Knapp on the dependence of accommodation and motility upon the refraction, 811; Dr. Eugene Smith on extraction of the anterior capsule, 811; Dr. Sterling Ryerson on the surgical treatment of trachoma, 811; Dr. Duane on tenotomy of the inferior oblique with a consideration of the different conditions that may call for the operation, 811; Dr. Dunbar Roy on phlegmon of the orbit simulating a malignant growth commencing in the ethmoidal cells, 811; Dr. H. V. Würdemann on diaphanoscropy of the eye or transillumination of the ocular coats, 811; Dr. T. D. Crowthers on the insanity of inebriety, 812; Dr. C. K. Clarke on dementia p. exoc, 812; Dr. E. E. Mentoul on proposed sterilisation of certain mental degenerates, 812; Dr. Schofield on mind and medicine, 812; Prof. Arthur Robinson on the study and teaching of anatomy, 866; Prof. J. Playfair McMurtry on a preliminary note on the valves of the iliac veins, 866; Prof. H. H. Donaldson on the architecture of the spinal ganglion, 866; Prof. A. Melville Paterson on the ligamentous supports of the pelvic viscera, 867; Dr. David Waterston on a preliminary note on the brain and skull in Mongolism, 867; Dr. George J. Jenkins on the morphology of the hip-joint, 867; Dr. Ross B. Harri on the development of the nerve elements in vertebrates, 868; Prof. T. G. Lee on the early development of gonads bursarius, 868; Dr. C. M. Shambaugh on the development of the stris vascularis of the cochlea, 869; Dr. Hamilton Wright on the nature of beri beri, 869; Prof. M. Nicolle on experimental glanders, 869; Dr. Armond Ruffer on the diagnosis of cholera asiatica, 870; Prof. M. Nicolle on the treatment of trypanosomiasis by the "colours of rezidine," 871; Prof. F. Mesnil on the treatment of trypanosomiasis by the "colours of benzidine," 871; Dr. Hewlett on the virus of small-pox and vaccinia, 871; Dr. Beattie on the bacteriology of rheumatic fever, 871; Dr. St. Clair Thomson on operations for correction of deviations of the nasal septum, 872; Dr. John O. Roe on operations for corrections of nasal septum, 872; Dr. George R. McDonagh on operations for correction of nasal septum, 873; Dr. Otto T. Freer on operations for correction of nasal septum, 873; Dr. Smurthwaite on headache: pathological conditions of the middle turbinal, a causal factor, 874; Dr. Perry G. Goldsmith on some unusual cases of frontal sinus suppuration, 874; Dr. Herbert Tilley on some considerations upon certain factors in diagnosis and treatment of suppurative lesions in nasal cavities, 874; Dr. Manau W. Loeb on a study of the anatomy of the accessory sinuses of the nose, based upon reconstructions of two heads, 875; Dr. Coakley on skiagraphy as an aid in the diagnosis and treatment of diseases of the accessory sinuses of the nose, 875; Dr. Norman Walker on the place and

position of dermatology in the medical curriculum, 876; Prof. J. Riven Hyde on the influence of light-hunger in the production of psoriasis, 876; Dr. Johnston on the evidence in favour of an autotoxic factor in production of bullous eruptions, 876; Dr. Robinson on some errors in the treatment of cutaneous cancer, 877; Dr. R. W. Taylor on the evolution of intra-primary pruriform syphilides, 877; Dr. Bulkeley on the wrong and right use of milk in treatment of skin diseases, 877; Dr. E. W. Lovett on osteogenesis imperfecta, 877; Dr. W. Ewart on abdominal stony in rickets, 878; Dr. Ashby on the medical aspect of pneumococcal infection, 878; Dr. C. L. Starr on the treatment of tuberculous abscess, 878; Dr. Blackader on rheumatism in children, 878; Dr. J. L. Morse on the dietetic treatment of entero-colitis, 879; Dr. Shaw on a study of the absorption of fat in infants, 879; Dr. Ralph Vincent on the milk laboratory in relation to medicine, 879; Dr. Edmund Cantley on congenital pyloric stenosis, 879; Dr. A. B. Vipond on the glandular system in infectious diseases, 881
 British Medical Association, meeting at Toronto: the annual exhibition, 744, 813; surgical instruments and appliances, 745; drugs, 746; foods and food products, 813; sanitary appliances, 813; mineral waters, beverage, &c., 813; publications, 813; miscellaneous, 813; review of, in *Annus Medicus*, 1813
 British Medical Benevolent Fund, 93, 391, 1090, 1235, 1618, 1749

- Spasm of muscles of lower part of trunk and thighs, 1072
- Spasmus nutans, 397; and dentition, 208; defective light theory in, 208; in infancy, 207
- Specialist, what is a? 258, 323, 463, 523, 682, 761, 882, 896, 555
- Specialism, what is? (leading article), 852

"Specific" treatment of dysentery, 1496
 Specimens, pathological, transmission by post of, 750
 Spectator experimental company, 759
 Spica, loss of, from fright; recovery under ethyl chloride, 1583
 Spelling, the new, 818, 970
 Spencer, Dr. H. R., treatment of extra-uterine pregnancy, 1443
 Spencer, Mr. W. G., cirsioid aneurysms, 1512; encapsulated sarcoma in pterygoid region, 1512; cystic dilatation of lower end of ureter containing calculi which became engaged intermittently in urethra, 1513
 Spencer-Smith, C., municipal muddles, 1400
 Spermin, 350
 Speyer, Mr. Edgar, honour to, 36
 Sphenoidal sinuses, a series of, 874
 Sphenoidal sinusitis, 1217
 Sphenoiditis, acute, 875
 Sphincters, contribution to the pathology of, in cranial and spinal injuries, 1286
 Spicer, Dr. R. H. Scanes, micrococcal neoformans vaccine, 517; inoperable cancer of throat benefited by injections of vaccine of micrococcal neoformans, 1218
 Spicer, Mr. W. T. Holmes, metastatic affections of the eye, 1145
 Spiess, Prof., injections of anaesthetics into cancer of mice, 1172
 Spiller, Dr. William G., the Eye and Nervous System: their Diagnostic Relations (review), 1355; syringomyelia, with a cavity traced from the sacral region to the upper part of the internal capsule, 802
 Spiller, Dr. W. S., psychic epilepsy, 743
 Spinal anaesthesia in surgery, 1160, 1729; (Annus Medicus), 1802
 Spinal caries, dorso-lumbar, 1515
 Spinal cord, plea for the study of the inter-medio-lateral tract in, 1352; sensory conduction in, of 15 cats, 810
 Spinal Curvature, Essay on the General Principles of the Treatment of (Dr. H. R. Heather Bigg) (review), 923
 Spinal curvature, ocular factors in, 666
 Spinal ganglion, architecture of the, 866
 Spinal and cranial injuries, contribution to the pathology of the sphincters in, 1286
 Spinal and Orthopaedic Hospital, Birmingham, 1099
 Spine, concussion of the, with some remarks on concussion in general (Mr. Edred M. Corner), 784
 Spine, congenital deformity of cervical, 1350
 Spine, motor-driver's (?) (Mr. W. J. Burroughs), 23
 Spine, osteomyelitis of, in an infant, 93
 Sprilla of the mouth (Mr. Kenneth W. Gosdy), 1281
 Spirits Acta, 1390
 Spirits, entered at Customs as "brandy," 242; discrimination of, by the Excise, 242
 Spiritualist's will, 1618
 Spiritualist and medical man, 697
 Spirochæta Duttoni, note on the structure of (Dr. J. W. Stephens), 438
 Spirochæta Duttoni, the passage of, from mother to fetus (Dr. Breinl and Dr. Kinghorn), 219
 Spirochæta, a new, found in a mouse, a preliminary note on a (Dr. Anton Breinl and Dr. A. Kinghorn), 651
 Spirochæta Laverani, 662
 Spirochæta pallida, 1217
 Spirochæta from syphills, yaws and granuloma pudendi, 1217; in mice, 954; nature of, 870
 Spirometric readings in stutters, 256
 Spleen, case of enlarged wandering, splenectomy (Dr. R. H. Lucy), 92
 Spleen, removal of, in a case of Banti's disease, 783; for traumatism, 1218
 Spleen, rupture of the, successful case of splenectomy for (Mr. G. S. Simpson), 364
 Spleen, rupture of, in a case of strychnine poisoning in a malarial subject, 515; in typhoid, 1230
 Splenectomy, a case of enlarged wandering spleen (Dr. R. H. Lucy), 92; successful case of, for rupture of the spleen (Mr. G. S. Simpson), 364; (Annus Medicus), 1786
 Splenic abscess in malarial fever, 1169
 Splenomegaly or myelopathic polycythæmia, further note to a case of (Dr. F. Farkes Splint, universal foot, 1345
 Spooner, Mr. William, sailors' foods, 807
 Spores, ringworm, staining and microscopical examination of, 1565
 "Spotted fever" in Glasgow, 60
 Weber, 1433, 1623, 1667
 Spratling, Dr. W. P., epilepsy, 743; study and treatment of epileptics, 1631
 Spriggs, Dr. E. I., dilatation of the heart, 1144; gastric ulcer, 1660; effects of meat diet on animals, 1779
 Spring apparatus for fracture of the clavicle, 1313
 Sprue, treatment of, 1009, 1659

Spurrier, Mr. A. H., Order conferred on, 179
 Sputum, tuberculous and articles infected by the tubercle bacillus, sterilisation of (Mr. T. Kirkland and Dr. M. S. Paterson), 426
 Squire, Dr. M. F., case of sprue treated by strawberries, 1669
 Squirrels, Palm, on a Parasite found in the White Corpuscles of the Blood of (Capt W. S. Patton) (review), 443
 Stafford, Mr. Thomas J., honour to, 1376
 Staffordshire, infantile mortality in, 423; sanitary progress in, 1878; hospital isolation of scarlet fever, 1737
 Stage fright, treatment of, 1552
 Stalder, Dr. E., Kaposi's disease, 1218
 Staines reservoir water and Thames water, 1226
 Staining encapsulated micro-organisms, a new method of, 190
 Staining and microscopical examination of ringworm spores, 1566
 Staircase, standardised, 1377
 Stamboul at the time of Ramadan, 1251
 Stammering, some observations on, and its treatment (Dr. R. A. Worthington), 769, 1196, 1186
 Standardisation of disinfectants, 123; of staircases, 1377
 Standardising Measurements of Trypanosoma, New Metrical Method of (Prof. A. Liegard) (review), 96
 Standing Orders of General Medical Council, revised edition, 1558
 Stanger, Mr. W., case of puerperal fever successfully treated with antistreptococcal serum, 654
 Stanley, Dr. A., health of Shanghai, 1537
 Stanley, Mr. L., cleansing of rag flock, 1563
 Staphylococci affections, 1135
 Staphylococcus albus and aseptic wounds, 1340
 Starch in rectal alimentation, 1266
 Stark, Mr. Joseph, after-effect of ethyl chloride anaesthesia, 257
 Starkey, Prof., water-supplies, 742
 Starling, Dr. H. J., observations on the arterial blood pressure in heart disease, 846
 Starr, Dr. O. L., treatment of tuberculous abscess, 878
 Starvation, deaths from, 1409; local, in treatment of cancer, 1642
 State hospitals, reform of out-patient department in Austria, 767
 State, medical service for Ireland, 1312, 1452, 1651; medicine and the official nomenclature of diseases, 307; neglect of science, 360; quarantine, in Italy, 471; registration of nurses, 170
 Statistical increase of lunacy, 814
 Statistics (see also Vital statistics)
 Statistics, consumption, in Ireland, 52; malaria, in Italy, 836; some Indian, 42; metropolitan lunacy, 1455; the unemployed, an interesting point, 750
 Stavros, A. X., acidity of the urine, 1281
 Steam, superheated, the therapeutic use of, in gynecology, atmochausis and zotokausis (Dr. Ludwig Pinnaus), 442
 Steamboats, the idle Thames, a suggestion, 1168
 Steamships, medical officers to, 1249
 Steel, hardening of, by a current of compressed air, 457
 Steele, Dr. William Stott, obituary, 1758
 Steele, Mr. D., malaria, 1384
 Stegomyia mosquito in yellow fever, 1531
 Stella, Dr. A., degeneration of Italian immigrants, 1266
 Stengel, Dr. A., some clinical manifestations, visceral and general, of arterio-sclerosis, 729
 Steinhilber, Mr. J. W., treatment of ringworm, 256
 Stenosis, congenital pyloric, 879; of lacrymal duct, 811
 Stenosis, mitral, and consecutive cardiac thrombosis, gangrene of both feet and legs due to embolism and thrombosis of the abdominal aorta in its entire extent the result of (Dr. H. W. Syers), 220
 Stenosis, mitral, a case of; death from embolism of six main arteries, 439
 Stephens, Dr. G. Arbour, stuttering, 256
 Stephens, Dr. J. W. W., note on the structure of spirochæta Duttoni, 438
 Stephens, Miss H., bequest, 1761
 Stephenson, Mr. S., on a form of amblyopia in young children consequent upon inherited syphills, 367; curious deformities of the eyelids, 1147
 Stephenson, Prof. W., puerperal sepsis, 228
 Steppay, medical officer's report on food supply, 1256
 Stereoscopic Atlas of Anatomy, the Edinburgh (Dr. D. Watson) (review), 444
 Sterile caseous matter, some observations on the effect of, in the treatment of tuberculous disease (Dr. P. Paterson), 493, 516
 Sterilisation of catgut by means of benzine, 755; of milk, Paris, 1248

Sterilisation of tuberculous sputum and articles infected by the tubercle bacillus (Mr. T. Kirkland and Dr. M. S. Paterson), 426
 Sterilisation, proposed, of certain mental degenerates, 812
 Steriliser and vaginal douche, combined, 445
 Sterilising urethral instruments, easy methods of, 1674
 Sternum, fracture of the, 936; dislocation and fracture of the (Annus Medicus), 1784
 Steven, Dr. John Lindsay, epidemic cerebro-spinal fever, with illustrative cases, 638; increased blood pressure, 729; cerebro-spinal meningitis, 802; cancer of œsophagus, 1074; appointment, 1476; dinner to, 1780
 Stevens, Dr. G. T., a Treatise on Motor Apparatus of the Eye, embracing an Exposition of the Anomalies of the Ocular Adjustments and their Treatment, with Anatomy and Physiology of the Muscles and their Accessories (review), 1779
 Stevens, Dr. T. G., dysmenorrhœa, 1667
 Stevens, Dr. J. B., fresh-air treatment, 742
 Stevenson, Mr. Roland Arthur, obituary, 1567
 Stevenson, T. H. C., on the correction of death-rates, 678; birth statistics, 1290
 Steward, Mr. F. J., case of primary pneumococcal peritonitis, 287
 Stewart, Surg.-Maj. D., volunteer officers' decoration, 678
 Stewart, Dr. James, of Montreal, death of, 1179
 Stewart, Dr. Purves, diagnostic value of examination of cerebro-spinal fluid, 1517
 Stewart, Mr. R. S., death of, 960
 Stewart, Dr. T. Grainger, diagnosis and localisation of tumours of the frontal regions of the brain, 1209
 Stewart, Dr. William, well-merited compliment to, 946
 "Stewart scholarships," three, for University of Melbourne, 274
 Sticker, Dr., endemic outbreaks of cancer, 1172
 Stiles, Mr. H. J., surgical treatment of congenital pyloric stenosis, 880; enterectomy for perforated typhoid ulcer and diffuse peritonitis, 1351; sacular theory of hernia, 1398
 Still, Dr. G. F., head-nodding with nystagmus in infancy, 207
 Still-born children, registration of, 1698
 Still's disease, 1516
 Stimuli, conditioned, various modifications and combinations of, 914
 Sting, weaver, 1235
 Stirling, Dr. J. W., sympathetic ophthalmia, 744
 Stirling, Prof. W., modes and means of nutrition, 1161
 Stock, Capt. F. G., endemic hæmaturia, 857
 Stockton, Dr. J., pulmonary tuberculosis in institutions for the insane, 1296
 Strickwell J., damages awarded against the Queensland Government, 1263
 Stockyards, Chicago, 323
 Stockyards, official report on the Chicago, in answer to the criticisms of THE LANCET, 109
 Stokes, Dr. Whitley Bland, obituary, 968
 Stokes-Adams disease, 364; (Annus Medicus), 1783
 Stokes-Adams disease and cardiac arrhythmia (Dr. John Hay and Dr. Stuart A. Moore), 1271, 1544
 Stomach and abdominal glands, lympho-sarcoma of, 1664
 Stomach and intestines, surgery of the (Annus Medicus), 1786
 Stomach, cancer of the, the early diagnosis of (Mr. C. Mansell Moullin), 773
 Stomach, cancer of the, on the treatment of (Mr. A. W. Mayo Robson), 419; surgical operations, 1810
 Stomach, chromaffine character of certain parietal cells of the, 869
 Stomach, malignant growth of the, 466; non-malignant ulcer of, 1231; operative treatment of non-malignant ulcer of, and its chief complications, 1437, 1590, 1650; (leading article), 1732
 Stomach, oozing of blood from the mucous membrane of the, or gastrostaxis (Dr. W. Hale White), 1189
 Stomach, rupture of, by inflation, 1178; ulcer of the, surgical treatment of, 1479; pathogenesis and pathology of ulcers of the, 870; volvulus of the, 312; wounds of the, treated by laparotomy, 1102
 Stomachs of normal mice and of mice suffering from cancer experimentally produced, determinations of amount of physiologically active hydrochloric acid in (Dr. S. M. Copeman and Dr. H. W. Hake), 1276
 Stomatitis and tonsillitis, 1220
 Stomatitis conveyed by a telephone mouth-piece, 1405; due to a mercurial injection given five months previously, 386, 462
 Stones, precursors, effect of radio-activity on colour of, 1177
 Stoney, Mr. G. L. E., death of, 528

Stoley, Mr. Percy B., the consultant and the general practitioner, 907
 Stoney, Dr. R. A., malunited supramalleolar fracture, 1443
 Stonham, Mr. C., Birds of the British Islands (review), 1001
 Stored water and diminution of pollution, 1226
 Storey, Mr. J. E., vaccination and antivaccinationists, 1166
 Stout, "nourishing," 1078; Reid's, 799
 Stovaine, 1102
 Stoves, gas, 1546
 Strain, eye, and its general symptoms, hints to the general practitioner on (Dr. J. Hinshelwood), 78
 Strangulated hernia operated on under local anaesthesia, 1436
 Strangulation of the appendix vermiformis in hernial sacs (Mr. H. S. Clogg), 1064
 Stratford, neglect of children at, 1178
 Straus, Mr. B. S., cancer research, 1563
 Strauss, Mr. N., treatment of milk in New York City, 1066
 Straw or grain chewing and actinomycosis, 1308
 Strawberries, packing and transport of, 106
 Strawberries, and longevity, 1335; in treatment of sprue, 1659
 Streams and oyster beds, prevention of bacterial contamination of, 1740
 Street ambulances, 121, 321, 1542, 1756
 Streeter, Dr. G. L., experiments on developing ear vesicle of tadpole, 867
 Streets, refuse in the, 710
 Streit, Dr. G., volvulus of the stomach, 312
 Streptococcal infections, certain important diseases associated with, 779
 Streptococcal inflammation of the pharynx, 25
 Streptococci, evolution of the (Dr. F. W. Andrews), 1415
 Streptococci pathogenic for man, a study of the (Dr. F. W. Andrews and Dr. T. J. Horder), 708, 776, 852, 1539, 1621, 1688
 Streptococci, proposed classification of, based upon all characters and including Gordon's tests, 711
 Streptococci infection, 871
 Streptococcus pyogenes, 775, 1419; salivarius, 776; anginosus, 777; faecalis, 778
 Stretton, Mr. J. Lionel, case of successful excision of a portion of the right lung for pulmonary tuberculosis, 161; two unique congenital deformities in the abdomen of the same patient, 440
 Stria vascularis of cochlea, development of, 869
 Striker, Dr., Die Blinddarmentzündung in der Armee von 1880-1900 (Perityphlitis in the Army 1880-1900) (review), 235
 Stricture, lacrymal, 811
 Strictures, multiple, of small intestine, probably of tuberculous origin, 1349
 Stridor, congenital laryngeal, 878
 Strong, T. E., lectures on the method of science, 660
 Strontium salts, observations on the action of, on the coagulability of the blood (Dr. J. E. Nias), 436
 Strophanthus and cratægus, 310
 Structure and functions of the amoeba, 738
 Struthers, Dr. J. W., case of chronic intussusception with complete inversion of the vermiform appendix, 1346
 Strychnine poisoning in a malarial subject, rupture of the spleen in a case of, 515
 Stuart, Dr. Francis H., puerperal sepsis, 809
 Stuart-Low, Mr. W., aural shield, 303; facial protective mask, 865
 Stocky, Dr. J. A., septal deviation, 874
 Students an address to (leading article), 538
 Students and Physicians, Medical, Text-book of Physiology for (Dr. W. H. Howell) (review), 377
 Students, practical joking by, at Göttingen, 529; strike of, at Lahore, 198, 286; study of French and German for medical, 624
 Students' Congress, British University, 127; International, 835
 Students' Handbook of Operative Surgery (Mr. W. I. de C. Wheeler) (review), 939
 Student's library, 543
 Student's Manual of Medical Jurisprudence and Public Health (Mr. G. H. Giffen) (review), 1149
 Study, post-graduate, 625
 Stutterers, aphroemetric readings in, 256
 Stuttering (Dr. W. S. Colman), 70, 256, 322, 463
 Stuporose conditions, 715
 Stypé-renal triturates, 1359
 Subcutaneous and intravenous injections of thyroid extracts in the normal animal, physiological effects of, 434
 Subcutaneous injections of extracts of suprarenal capsules, 351
 Subcutaneous rupture of Poupert's ligament and laceration of peritoneum, 1436

Submucons (or window) resection operation for correction of deflections of the nasal septum (Dr. E. Furniss Potter), 643
 Submucous resection for deviations of nasal septum, 875
 Submersion, gangrene of the lung after, 104
 Subscribers' letters and hospital abuse, 517
 Suburban death-rates, 37
 Subways (New York), condition of the air of, 131
 Sudor Anglicus, 1374
 Sugar in urine, the detection of, and its significance in connexion with life assurance (Dr. A. M. Kellas and Dr. F. J. Wethered), 1058, 1136
 Suggestion, therapeutic application of, 450; in treatment of stage fright, 1552
 Suicide and its methods, 311
 Suicide or homicide, 464
 Suicide, race, 1635; in Ontario, 530
 Sulcus occipitalis lunatus in apes and human brains, 1314
 Sulle Leggi Statistiche del Suicidio, Professor Morselli, 311
 Sullivan, Dr. W. C., Alcoholism; a Chapter in Social Pathology (review), 1730
 Sulphate of soda, is it a true intestinal antiseptic? (Mr. J. Maberly), 1280
 Sulphate of sodium and magnesium as intestinal antiseptics, 1293
 Sulphur, acid gas stoves, 1363; and x ray shadows of calcium, 141
 Sultán, recent illness of the, 529
 Summer diarrhoea bacillus and flies, 513
 Summer diarrhoea in children, and Liverpool Royal Infirmary, 260
 Summer, June, July, and August, 763; urban infant mortality in, 1224
 Summers, Dr. Walter (Bendigo), miner's disease, 1253, 1757
 Sunday, needs of the body on (Dr. H. Handford), 1283
 Sunday holiday, 1454; observance, 1230
 Sunderland, school hygiene, 119
 Sunninghill drainage, 1536
 Sunshine, September and October, 1299; at Sandown, Isle of Wight, 1472
 Sunstroke, ice-water enemata in treatment of, 1740
 Superheated steam in gynaecology, 442
 Suppuration and streptococcal infection, 779
 Suppuration of the middle ear, chronic, the cure of without removal of the drum or ossicles or the loss of hearing (Mr. C. J. Heath), 363
 Suppurative tuberculous arthritis, saline baths in treatment of, 195
 Suprapubic dressing (Dr. G. H. Coit), 860
 Suprarenal capsules, cirrhosis of the, and interstitial nephritis in an infant five weeks old (Dr. G. Carpenter), 1208
 Suprarenal capsules, functions of the, 350; lesions of the, 1594
 Suprarenal extract, beta-eucaine, and phenol, "anaesthunder," 1435
 Surdus in Search of his Hearing (Mr. E. Yellon) (review), 1077
 Surgeon's breath, infection from, 347
 Surgeons and assistants in operations, hands of (Mr. A. E. J. Barker), 345
 Surgeons and shipping companies, 1625
 Surgeons, civil, South African, 124
 Surgery (review of, in *Annus Medicus*), 1784
 Surgery and Medicine, Birmingham School of, 1165

 Surgery, Minor and Operative, including Bandaging (Dr. H. B. Wharton) (review), 444
 Surgery of central nervous system, palliative procedures, 484; curative procedures, 485
 Surgery of wounds of the heart, 327
 Surgery, Operative, Students' Handbook of (Mr. W. I. de C. Wheeler) (review), 939
 Surgery, then and now in (Mr. C. A. Ballance), 1043, 1171
 Surgery, spinal anaesthesia in, 1160; novocaine in, 1404, 1473
 Surgical Congress, Frerob, 886
 Surgical Diagnosis, Aids to (Mr. H. W. Carson) (review), 1448
 Surgical forms of ileo-caecal tuberculosis, 1592
 Surgical or medical treatment power to compel, 318
 Surgical reform, 1829
 Surgical Suggestions: Practical Brevities in Diagnosis and Treatment (Dr. W. M. Brickner and Dr. E. Moschcowitz) (review), 939
 Surgical tuberculosis, treatment of (Mr. V. Warren Low), 74

Surgery, address in, British Medical Association meeting at Toronto, 484; (leading article), 511
 Surgery, Gastric (Mr. Herbert J. Paterson) (review), 1668
 Surgery, plastic, of the renal pelvis, a contribution to the (Mr. J. W. T. Walker), 373
 Surgery, practical, post graduate instruction in, 476
 Surrey, report of medical officer of health of, 1394; county asylum, Brookwood, annual report of, 252; county council, commutation of working expenses of M.O.H., 454
 Suspensio uteri, 735
 Sussex County Hospital, endowment, 949
 Sutcliffe, Mr. W. G., three cases of twisted pedicle, 660
 Sutherland, Dr. W. G. and Worhampton Friendly Societies Medical Institute, 535; Mr. C. C. Becke on, 535
 Suture of the arteries, 1102
 Suture of perforating wound of the heart; death on the eleventh day (Mr. F. T. Travers), 706
 Swansea and Cardiff hospitals, 261, 398
 Swansea, asylum, 833; consecration of "Dr. James Griffith Hall Lodge," 287; infantile mortality in, 261; refuse destructor, 860; water supply, 51
 Swanton, Dr. J. H., ovarian cystoma, 1352; abdominal hysterectomy f.r. fibroid under spinal anaesthesia, 1729
 Sweat glands, secretory fibres to the, 23
 Sweating sickness, or miliary fever, 1374
 Sweden (Swedish Touring Club) (review), 1000
 Swedish, bread (Schumacher), 1359; touring club, 1000; system of physical culture and its therapeutic application, 1444, 1764
 Sweating, Dr. M. D., diphtheria at Frinton, 1031; sanitary condition of Dartmoor villages, 1160
 Swellings, multiple, on bones of one lower extremity, 1346
 Swindling and quackery, 835
 Swiss universities, foreign students at, 1250
 Switzerland and vaccination, 133
 SWITZERLAND. CORRESPONDENCE FROM.—
 Diphtheritic ophthalmia, 1250—Foreign students at Swiss Universities, 1250
 Sydenham, Thomas, 1395
 Sydenham's chorea, 982
 Sydney: action for burns by Tallerman bath, 267; case of leprosy in, 1507; coast hospital condemned, 1253; medical man assaulted in, 1315; milk-supply of, 1315; plague in, 530, 903, 1479; scarlet fever in, 903; University of, 531
 Syers, Dr. H. W., gangrene of both feet and legs due to embolism and thrombosis of the abdominal aorta in its entire extent, the result of mitral stenosis and consecutive cardiac thrombosis, 220; Physiology of the Nervous System (review), 504; obituary, 1181
 Sykes, Dr. J. F. J., ice-cream poisoning, 667; health of St. Pancras, 1237
 Sym, Dr. W. G., Kronlein's operation, 1665; glioma, 1665
 Symbols, the apothecary's, 453
 Symes-Thompson, Dr. Edmund, obituary, 1555
 Symmelian monster (symposium dipus), 865
 Symmers, Dr. William St. Clair, foreign order to, 108; rupture of the inferior vena cava, 1070; remarkable case of bilharziasis, 1178
 Symmetrical arthritis of hip joints in a boy of eight, 1216
 Symonds, Mr. C. J., case of traumatic separation of head of femur, 1215; multiple strictures of small intestine, probably of tuberculous origin, 1349; appointments, 1539
 Sympathetic ophthalmitis, preventive treatment of, 744
 Symptom, a curious, 1637
 Symptoms, eye strain and its, hints to the general practitioner on (Dr. J. Hinshelwood), 78
 Synthesis, new, of tyrosine (Dr. P. W. Latham), 1563
 Syphilis nephritis in an infant, 1516
 Syphilides, intraprimary prodromal, the evolution of, 877
 Syphilis and venereal disease in Sivas, 690
 Syphilis, inherited, on a form of amblyopia in young children consequent upon (Mr. S. Stephenson), 357
 Syphilis, Aachen treatment of, 1205; auto-inoculation of, 1756; damages paid by a father to nurse infected from his child (Paris), 1313; hot-air baths in, 1205; hygienic measures against, 46, 190; in respectable women, 1102; intramuscular injection of mercury in, 1204, 1787; icterus in, 648, 1205; prodromal lesions, 877; acquired, 1565
 Syphilis, so called venereal, and its treatment (Col. F. J. Lambkin), 1203, 1399

- Syphilis, yaws and granuloma pudendi, spirochete from, 1217
- Syphilitic infection and civil responsibility, 327
- Syphiloma, a case of cardiac, with bradycardia and obstruction of the inferior vena cava (Dr. Charles W. Chapman), 219
- "Syphon" gas stove, 1361
- "Syphon Radiator" gas stove, 1361
- Syrin, ancient medical MSS from, 1157

LIST OF ILLUSTRATIONS.

- Three Maps accompanying a paper by Dr. J. L. Todd entitled A Means of Checking the Spread of "Sleeping Sickness"—viz., 1, Distribution of Human Trypanosomiasis and Tsetse Flies in Africa, 7; 2 and 3, Distribution of "Sleeping Sickness" in the Congo Free State, 1897 and 1905, 8
- Three Figures illustrating Busaco and the Future of Portuguese Health Resorts—viz., Fig. 1, the Monumental Palace and Hotel, showing the Stone Carving and the Sheltered Gallery round the Building, 48; Fig. 2, Garden in front of the Hotel showing the Semi-tropical Vegetation, 49; Fig. 3, the Queen of Portugal's Villa and the Chimes of the Old Carmelite Monastery, with cedar trees that are some centuries old in the background, 50
- Tracing illustrating a paper on the Treatment of Surgical Tuberculosis, by Mr. V. Warren Low, 77
- Photoprint of specimen of Bulla three days old, magnification about 37, accompanying a paper on Two Cases of Epidermolysis Bullosa, by Dr. Agnes F. Savill, 87
- Diagrammatic representation of Fracture of the Upper End of the Tibia from Indirect Violence, described by Mr. R. Lawford Knaggs, 89
- Diagram and Photoprint illustrating a Simple Form of Clinical Viscometer, described by Dr. A. Du Pré Denning and Dr. J. H. Watson, 89
- Illustration of the "Witch" Dust Extractor, 96
- Eight Photoprints accompanying a paper on the X Ray Shadows of Cystic and Xanthic Oxide Calculi, by Mr. H. Morris—viz., Fig. 1, Oxalate of Lime, 141; Figs. 2 and 3, Cystin with Phosphate of Lime, 141; Fig. 4, Cystin, D 9, 141; Fig. 5, Cystin, 142; Fig. 6, Cystin, D 8, 142; Fig. 7, Xanthin, 142; Fig. 8, the Shadow of a Uric Acid Calculus to show the slight intensity of shadow as compared with the shadows of cystin and xanthin, 142
- Illustrations accompanying a paper on the Influence of an Excessive Meat Diet on Growth and Nutrition, by Dr. D. C. Watson—viz., Fig. 1, showing the Relative Size of Two Male Rats of the same litter after being Fed for Three Months on Bread and Skim-milk (a) and Ox-flesh (b), 146; Fig. 2, Showing state of Development of the Progeny of Normally Fed (bread and milk) Rats (a) in Comparison with Rats of the same age Bred on a Flesh Diet (b), 146; eight Charts illustrating (1 and 2) Influence of an Ox-flesh Diet on Young Rats; (3 and 4) Influence of a Horse-flesh Diet on Young Rats; (5) Influence of a Horse-flesh Diet on Adult Rats; (6) Effects of Bread and Sweet Milk Diet on Young Rats; (7) Influence of Bread and Skim-milk Diet on Young Rats; (8) Recuperative Power in Second Generation of Meat-fed Rats, 146, 147, 148, 149
- Six Diagrams illustrating a paper on the Radical Cure of Femoral Hernia, by Mr. Aslett Baldwin—viz., Fig. 1, An Incision being made on to the point of a Director which has been passed up the Crural Canal and its point tilted forwards about half an inch above Poupart's Ligament; Fig. 2, Sinus Forceps passed through the opening above Poupart's Ligament, behind the Ligament, and through the Saphenous opening, and made to grasp the Fundus of the Sac; Fig. 3, the Sac pulled out through the opening above Poupart's Ligament; Fig. 4, Needle threaded as described passed through the Neck of the Sac, through the opening above Poupart's Ligament, across the Transverse Ramus of the Pubes, through the Pectineus Muscle, and out through the Saphenous opening; Fig. 5, the Sac has been passed back through the opening above Poupart's Ligament and rests behind the latter and the Transversalis Fascia; Fig. 6, the Two Ends of the Thread are tied, fixing the Sac in its place and obliterating the Crural Canal, 151
- Illustration of a Fish-tail Tube Spatula accompanying an article on the Operative Treatment of Laryngeal Papillomata in Children, by Dr. D. E. Paterson, 155
- Semi-diagrammatic representation of the parts in a case of Congenital Abnormality of the Genito-urinary Organs, described by Mr. G. F. D. Smith and Mr. A. L. H. Smith, 157
- Two Diagrams illustrating a Case of Appendix Abscess, under the care of Mr. Russell J. Howard—viz., Fig. 1, Showing Position of Appendix, 161; Fig. 2, Showing Position of Abscess Cavity and Perforation of Duodenum, 161
- Illustration of a Modification of Letter's Urethroscope, described by Mr. W. Wjndham Powell, 169
- Illustration of a New Retractor made for and described by Dr. W. Blair Bell, 169
- Diagram illustrating a Report of Tests of Grates submitted for the Consumption of Anthracite Coal, 182
- Two Photoprints illustrating a paper on Appendicitis and Gangrene of the Vermiform Appendix considered as separate Diseases, by Mr. J. D. Malcolm—viz., Fig. 1, Appendix removed 14 days after Recovery from an Inflammatory Attack, 214; Fig. 2, Appendix with Glands, 215
- Four Figures illustrating Flagellated Protozoa from a case of Perineal Abscess, described by Dr. E. H. Hunt, 216
- Photoprint showing General Appearance of Gangrenous Lesion in a case of Gangrene of both Feet and Legs due to Embolism and Thrombosis of the Abdominal Aorta in its entire extent, the result of Mitral Stenosis and Consecutive Cardiac Thrombosis, by Dr. H. W. Syers, 220
- Photoprint showing Shapes and Facets of Gall-stones, accompanying a case of Gall-stones of Large Size passed by the Rectum, by Dr. W. E. C. Dickson, 221
- Two Diagrams accompanying a paper on the Possible Importance of Earth-worms as a Factor in the Spread of Disease, by Dr. Charles F. Fraser—viz., Fig. 1, Parasitic Nematode of Worm; Fig. 2, Trichina Spiralis, 224
- Illustrations of the "Rastilon" Ambulance Spring, 236
- Seventeen Photoprints accompanying articles on Medicine in Toronto—Fig. 1, the First Medical School in Upper Canada, 263; Fig. 2, Portrait of Dr. Christopher Widmer, 269; Fig. 3, Portrait of Dr. John Rolph, 270; Fig. 4, Portrait of Dr. James H. Richardson, 271; Fig. 5, Portrait of Dr. Edward M. Hodder, 331; Fig. 6, Portrait of Dr. William Charles Gwynne, 332; Fig. 7, the University of Toronto, 333; Fig. 8, Portrait of Dr. R. A. Reeve; Fig. 9, Portrait of Dr. James Bovell, 405; Fig. 10, Ward in Sick Children's Hospital, 406; Fig. 11, Toronto General Hospital, 406; Fig. 12, Operating Theatre in Toronto General Hospital, 407; Fig. 13, Plan of the University Buildings, 467; Fig. 14, the Biological Building, 468; Fig. 15, the Medical Building, 468; Fig. 16, Portrait of Prof. A. B. Macallum, 469; Fig. 17, Portrait of Dr. A. Primrose, 470
- Three Illustrations accompanying a paper on Removal of a Cerebral Tumour (Endothelioma) which had invaded the overlying Cranial Bone, by Prof. Barling—viz., Fig. 1, Diagram of a Coronal Section through Tumour, 232; Fig. 2, Photomicrograph of Lower Marginal Part of Tumour, 233; Fig. 3, Photomicrograph of a Typical Part of Tumour, showing its purely Cellular Structure and Whorled and Irregular Arrangement of Spindle Cells, 234
- Two Charts showing Blood Pressure accompanying a paper on Blood Pressure and Pigmentation in Addison's Disease, by Dr. Short, 236
- Six Photoprints illustrating a paper on Some of the Pseudo-parasites of Cancer, by Dr. A. S. Grunbaum—viz., Fig. 1, Included Cell Degenerating and Shrinking; Fig. 2, Included Cell lying within Vacuole in another Cell; Fig. 3, Included Cell Dividing; Fig. 4, Cell showing "Spermatid Vesicle" and Nuclear Degeneration; Fig. 5, Yeast Cell included in Pulmonary Cell of Mouse; Fig. 6, Cell Degeneration simulating Fig. 5, 235
- Diagram illustrating an Aural Shield, described by Mr. W. Stuart-Low, 303
- Photoprint showing Cannula, Probes, and Forceps, accompanying a paper on the Cure of Chronic Suppuration of the Middle Ear without Removal of the Drum or Vesicles or the Loss of Hearing, by Mr. Charles J. Heath, 304

[List of Illustrations continued on next two pages.]

LIST OF ILLUSTRATIONS—(Continued).

- Five Illustrations representing Calves and Human Hearts accompanying a paper on the Auriculo-ventricular Bundle of the Human Heart, by Dr. A. Keith and Mr. M. W. Fiack, 360, 361, 362, 363
- Two Illustrations accompanying an article on a Successful Case of Splenectomy for Rupture of the Spleen, by Mr. Graham S. Simpson—viz., Fig. 1, Antero-external Aspect of Spleen showing Laceration of Lower Pole, 365; Fig. 2, Postero-internal Aspect of Spleen showing Laceration and Stripping of Capsule, 365
- Illustration accompanying a paper on Some Unusual Forms of Anæmia in Childhood, by Dr. T. R. C. Whigham and Mr. A. N. Leatham, 369
- Seven Diagrams illustrating Steps in Plastic Operation upon the Renal Pelvis, accompanying a Contribution to the Plastic Surgery of the Renal Pelvis, by Mr. J. W. T. Walker, 373, 374
- Illustration of a Two-way Peritoneal Irrigator, described by Mr. H. M. W. Gray, 379
- Portrait of the late Professor Brouardel, 409
- Three Illustrations accompanying Observations on the Life-history of Leucocytes, by Mr. C. E. Walker—viz., Fig. 1, a Somatic Division Figure, 428; Fig. 2, a First Mitotic (heterotype) Division Figure, 429; Fig. 3, a Second Mitotic (homotype) Division Figure, 429
- Three Diagrams illustrating the Sterilisation of Tuberculous Sputum and Articles Infected by the Tubercle Bacillus, by Mr. T. Kirkland and Dr. M. S. Paterson—viz., Fig. 1, Sputum Steriliser with Cover on, 427; Fig. 2, Sputum Steriliser with Cover off, 427; Fig. 3, Tank for washing Sputum Pots, 428.
- Diagrammatic Representations of various Forms of Spirochæta Duttoni, accompanying a Note on the Structure of Spirochæta Duttoni, by Dr. J. W. W. Stephens, 438
- Illustration of Thimbles for making Wool Mops, described by Mr. E. C. Baber, 445
- Illustration of a Combined Vaginal Douche and Steriliser, described by Mr. C. St. Aubyn-Farrar, 445
- Diagram of a new Post-nasal Syringe, described by Dr. F. H. Burton-Brown, 445
- Four Diagrams accompanying an address on the Technique of Operations on the Central Nervous System, by Sir Victor Horsley—viz., Figs. 1, 2, and 3, from Frazier's "Guide to Operations on the Brain"; Fig. 4, Brain of Macaque Monkey, showing Effect of Vein, Ligature for Displacement of Hemisphere, 488
- Photoprint of a Preparation made from the Blood of a case of Jaundice, illustrating an article on two cases of Multiple Infection, by Mr. G. C. Chatterjee, 499
- Diagram showing a "Scissors Shield" for Circumcision, described by Dr. H. Dutch, 508
- Diagram showing a Uterine Cotton-wool Forceps, described by Dr. J. C. Robertson, 508
- Five Diagrams illustrating the Submucous (or Window) Resection Operation for Correction of Deflections of the Nasal Septum, by Dr. E. Furniss Potter, 644
- Photoprint accompanying Note on Successful Removal of a Large Hygroma in a Child aged Three Weeks, by Dr. J. Cropper, showing Appearance of Child before Operation, 652
- Illustration of a New Metal Catheter Gauge, described by Mr. Cecil H. Leaf, 659
- Illustration of the Norledge Extension Apparatus, described by Dr. C. D. Muspratt, 659
- Illustration of a Back-flow Catheter for Urethral Irrigation, described by Dr. R. W. Hey Groves, 659
- Photoprints illustrating Articles on Portuguese Quarantine Regulations—viz., Fig. 1, the Boat containing the Clayton Disinfecting Apparatus and the Pipes through which the Fumes can be sent into all the Disinfecting Chambers of the Station on Shore or into the Hold of a Ship anchored in the Harbour of Leixões (Oporto), 685; Fig. 2, Map of River Tagus, 763; Fig. 3, the New Maritime Disinfecting Station at Lisbon, 763
- Three Illustrations accompanying paper on Suture of Perforating Wound of the Heart, Death on the Eleventh Day, by Mr. F. T. Travers—viz., Fig. 1, Showing Lines of Fracture in Sternum, 708; Fig. 2, Appearance of Heart after Removal, 707; Fig. 3, Diagrammatic View of Wound, 708
- Thirteen Diagrams illustrating a paper on the Pulse in Aortic Disease, the Relation of Pulse Curves to Blood Pressure, by Dr. Thomas Lewis, 714 717
- Diagram of Inhaler illustrating an article on a New Method of Administering an Anæsthetic through a Tracheotomy Tube, by Dr. Walter P. Cockle, 717
- Two Photoprints illustrating a paper on Successful Treatment of a Case of Thoracic Aneurysm threatening to Rupture Externally, by Mr. Eric E. Young, 783, 784
- Photoprint illustrating a case of Osteitis Deformans with Huntington's Chorea, by Dr. C. Mackey, 788
- Five Tracings illustrating a paper on Some Observations on Stammering and its Treatment, by Dr. R. A. Worthington, 790, 793, 794
- Three Charts illustrating cases in an article on Observations on the Arterial Blood Pressure in Heart Disease, by Dr. H. J. Starling, 848-850
- Seven Charts accompanying a paper on a Study of the Streptococci Pathogenic for Man, by Dr. F. W. Andrews and Dr. T. J. Horder, 782, 853, 854
- Illustration of Suprapubic Dressing, oval pattern, described by Dr. G. H. Colt, 860
- Illustration of a Facial Protective Mask described, by Mr. Stuart-Low, 865
- Diagram of a new Gastro-enterostomy Clamp, described by Dr. T. G. Atkins, 865
- Four Charts accompanying a paper on The Injection of Antitoxin in Diphtheria by the Intravenous Method, by Mr. A. O. Bisson, 930
- Diagrams illustrating Nutritive Values of Certain Articles of Diet accompanying a paper on Notes on Purin-free Diets, by Dr. W. A. Potts, 934
- Four Illustrations accompanying an article on a Visit to Professor Czerny's Cancer Institute—viz., Fig. 1, Façade of Hospital, 957; Fig. 2, Plan of First Floor of Hospital, 957; Fig. 3, Plan of Ground Floor of Research Building, 957; Fig. 4, Portrait of Professor Vincent Czerny, 958
- Two Photoprints and three Diagrams illustrating a Clinical Lecture on a Case of Infective Endocarditis involving the Pulmonary Valves and associated with Imperfection of the Interauricular Septum, by Dr. T. W. Griffith, 974, 975
- Five Illustrations accompanying a Contribution to the Pathology of Chorea, by Dr. F. J. Poynton and Dr. G. M. Holmes, 984, 985, 986
- Two Figures accompanying Some Observations on Enlarged Veins in Children, by Dr. A. G. Gibson, 1054
- Diagram illustrating paper on the Detection of Sugar in Urine and its Significance in Connexion with Life Assurance, by Dr. A. M. Kellas and Dr. F. J. Wethered, 1061
- Three Figures illustrating a Method of taking Impressions of the Weight-bearing Surface of the Foot, by Dr. W. D. Lawrie, 1067
- Illustration of an Improved Vaccinator, described Dr. by A. A. Macketh, 1079
- Three Illustrations of Pelvic Pedicle Needles with Ring Lever Handles, described by Mr. W. S. Handley, 1079
- Four Tracings from Radial and Jugular Vein illustrating an article on Some Aspects of Dilatation of the Heart, by Dr. A. M. Gossage, 1125, 1127
- Six Charts accompanying a paper on a Series of Cases treated by the Injection of Bacterial Vaccines, by Dr. E. Turton and Dr. A. Parkin—viz., Fig. 1, showing Temperature and Opsonic Index, 1132; Figs. 2, 3, 4, 5, and 6 showing Opsonic Indices, 1132, 1134
- Five Diagrams illustrating a paper on the Saccular Theory of Hernia and the Radical Operation, by Mr. R. H. Russell, 1199, 1200, 1201
- Four Photoprints illustrating an address on Adolescent or late Rickets, by Mr. H. H. Clutton, 1268
- Three Charts, six Tracings, and two Diagrams accompanying a paper on Stokes-Adams Disease and Cardiac Arrhythmia, by Dr. John Hay and Dr. Stuart A. Moore, 1275, 1274, 1275
- Four Figures illustrating a paper on the Treatment of Laryngeal Tuberculosis, by Mr. H. Barwell—viz., Fig. 1, Infiltration of Arytenoids; Fig. 2, "Turban-shaped" Epiglottitis; Fig. 3, Infiltration of Cords, Ulcer on Vocal Process; Fig. 4, Interarytenoid Granulations arising from a Tuberculous Ulcer, 1278
- Illustrations accompanying an address on Longevity and the Means of Attaining It, by Sir Lauder Brunton—viz., Fig. 1, Cell from Brain of a Woman, aged 100 years, being Devoured by Microphages, 1333; Fig. 2, Section of Renal Tubule invaded by Microphages, from body of an old man, aged 90 years, 1333; Fig. 3, Diagram of Effect of Arterial Pulse in aiding Circulation in Veins and Self-massage of Artery Itself, 1334; Fig. 4, Sphygmogram from Radial Pulse, 1334

LIST OF ILLUSTRATIONS—(Continued).

- Ten Illustrations accompanying a paper on Some Contributions to the Orthopedic Armamentarium, by Mr. E. Muirhead Little, 1343, 1344, 1345
- Illustrations accompanying a paper on Gas Stoves, an Inquiry into their General Efficiency, by the Coal Smoke Abatement Society—viz., Fig. 1, Bunte's Burette, 1362; Fig. 2, Bottle for testing for Carbon Monoxide, 1362; Fig. 3, Temperature Chart, 1370; Figs. 4, 5, 6, and 7, Velocity Tests, Temperature Charts, 1370, 1371, 1372
- Illustrations accompanying a paper on the Description of a Heart showing Gummatous Infiltration of the Auriculo-Ventricular Bundle, by Dr. A. Keith and Dr. C. Miller—viz., Fig. 1, Heart, showing Septal Wall of Right Auricle and Ventricle, 1430; Fig. 2, Left Side of Heart is removed, 1430
- Illustration of a Modified Chloroform Mask, described by Mr. T. R. St. Johnston, 1450
- Portrait of Dr. Gustave Isidore Schorstein, 1481
- Chart showing Incidence of Dysentery per 1000 British Troops in India and Number constantly Sick from the Disease per 1000 of Strength during Decennium 1894-1903, accompanying a paper on Tropical Dysentery, by Capt. E. J. Blackham, 1493
- Four Charts showing Opeonic Index accompanying a contribution to the Study of Phlyctenular Ophthalmia by Dr. J. B. Nias and Mr. L. Paton, 1500, 1501
- Four Charts accompanying an article on Cerebro-spinal Meningitis in the Sudan, by Dr. C. Ll. Nedwill, 1506
- Illustration to an article on a case of Cesarean Section followed by Removal of a Fibroid Tumour which filled the Pelvic Cavity, by Dr. H. R. Andrews, 1511
- Photoprint accompanying an abstract of a clinical lecture on a case of Lingual Goitre, by Mr. G. H. Makins, 1569
- Twelve Illustrations accompanying a paper on Further Observations on Endemic Goitre, by Capt. E. McCarrison—viz., Figs. 1, 2, 3, and 4, Photoprints of Cases Before and After Treatment by Thymol, 1573; Figs. 5, 6, 7, 8, 9, and 10, Organisms found in Faces of Persons suffering from Goitre, 1575; Fig. 11, Shell with 20 Spines, 1576; Fig. 12, Sketch Map of Left Bank of Chitral River, 1576
- Four Photoprints of Brain illustrating a case of Epileptic Idiocy associated with Tuberosc Sclerosis of the Brain, by Dr. Margaret B. Dobson, 1584
- Illustrations of Sections of Cranium and Bony Rib of Rats and Section of Shaft of Radius of an Infant accompanying a paper on the Influence of an Excessive Meat Diet on the Osseous System, by Dr. D. Chalmers Watson, 1587
- Illustration of the "Bos" Direct Current Portable Ozoniser, 1598
- Illustration of a Radium Applicator, described by Mr. J. Elrick Adler, 1598
- Two Diagrams illustrating Loss of Sensation accompanying an article on Some Observations on Paralyzes of the Brachial Plexus, by Dr. W. B. Warrington and Mr. Robert Jones, 1645, 1646
- Illustration of a Compact X Ray Shield specially adapted for the Treatment of Ringworm, described by Dr. Agnes F. Savill, 1670
- Illustration of a Modified Artery Forceps, described by Dr. F. F. Carroll, 1670
- Eight Photoprints illustrating a paper on Art and Medicine, by Dr. Leonard Mark—viz., Fig. 1, Detail from Raphael's Cartoon "St. Peter and the Lame Man," 1703; Fig. 2, "St. Roch and the Angel," 1704; Fig. 3, "St. Martin Dividing his Cloak," 1706; Fig. 4, "The Pool of Bethesda," 1705; Fig. 5, Great Seal of Edward the Confessor, 1706; Fig. 6, the Dwarf Turoid in the Bayeux Tapestry, 1707; Fig. 7, An Ancient Doctor's Signboard, 1707; Fig. 8, Antique Statuette of a Dwarf, 1708
- Four Photoprints accompanying an article on Large Arterio-venous Aneurysm of the Neck treated by Excision, by Mr. James Berry, 1715
- Two Photoprints showing Sections of Heart, illustrating a note on Three Interesting Heart Cases, by Dr. E. G. White, 1716, 1717
- Three Diagrams illustrating the Treatment of Ovarian Prolapse by Shortening the Ovarian Ligament, by Dr. Victor Bonney, 1717, 1718
- Illustration of Fenestrated Speculum accompanying an article on An Operation for the Cure of Prolapsus Ani and Internal Hemorrhoids, by Dr. D. Newman, 1720
- Five Photoprints illustrating a paper on Some Pathological Considerations of Extra-uterine Pregnancy, by Dr. S. J. M. Cameron—viz., Fig. 1, Section to Show Tip of a Villus (Below) and Decidual Formation in Tubal Wall, 1776; Fig. 2, Syncytial Masses, 1776; Fig. 3, Vessels and Degenerate Wall, Tips of Villus, Fibrinous Layer with Leucocytes, 1776; Fig. 4, Twin Tubal Pregnancy, 1777; Fig. 5, Gravid Tube and Ovarian Cyst from case of Bilateral Ovarian Cysts with Ectopic Pregnancy in One Tube, 1777

END OF THE SECOND VOLUME FOR 1906.

The Harveian Lecture

ON

MYELITIS.

*Delivered before the Harveian Society of London on
March 22nd, 1906.*By J. S. RISIEN RUSSELL, M.D. EDIN.,
F.R.C.P. LOND.,PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON; AND
PHYSICIAN TO OUT-PATIENTS AT THE NATIONAL HOSPITAL
FOR THE PARALYSED AND EPILEPTIC.

MR. PRESIDENT AND GENTLEMEN,—Let me first thank you, Sir, and the Council of the Harveian Society for the great honour you have done me in inviting me to give this Harveian lecture. It would in any case be an honour to be allowed to deliver a lecture before this society but the honour is greatly enhanced by the fact that this is not the occasion of an ordinary lecture, for I am entrusted with a task the object of which is to do homage to the memory of one of the greatest men we are fortunate enough to be able to number as one of our profession. Harvey's great discovery is ever fresh in our memories and no such lecture as this is needed to perpetuate a name that will live for all time. Nevertheless, such occasions are good if for no other reason than that they serve to incite us to emulate the example of the great men of the past by prosecuting researches in the hope that we may discover fresh truths. Although we are but pygmies when compared with those giants and although we cannot all hope to make great discoveries, yet every little helps, and every opportunity for research if properly cultivated must result in the discovery of new truths which must be to the ultimate advantage of the human race.

In the branch of medicine to which I have devoted more especial attention it would have been possible for me to select a subject the title of which would have suggested a closer connexion with the discovery of the man whose name we honour to-night. In reality, however, it will soon become obvious to you that under the title of "myelitis" I shall have much to say that is very intimately related to the circulation of the blood. One of the chief contentions that I hope to urge upon you is that much of what is spoken of as myelitis is in reality the outcome of interference with the nutrition of the spinal cord by the cutting off of the blood-supply from the affected area. Even if my subject had not been in any way related to Harvey's discovery, however, no apology would have been needed, as I am assured that the council of the society does not expect the lecturer to select his subject with this end in view but that all that is expected of him is that he should deal with some matter of scientific or practical interest. I hope that the subject I have chosen may prove to be both scientific and practical, and, as I have already said, it certainly embraces much that is very intimately related to the discovery of the circulation of the blood.

Myelitis has been chosen as the subject not only because centred around it is much that is of practical as well as of scientific interest but also because I am convinced that many errors cling about the name. It was my anxiety not to miss such an opportunity of giving utterance to my convictions on this point that emboldened me to accept so great a trust and to attempt to deliver this lecture, although conscious that I should fall far short of the standard which an occasion of the kind demands. Many have been the misgivings that have haunted me since I accepted the responsibility, for I have daily become more conscious of the shortcomings of this lecture. Let me at once crave your pardon for the many defects which you will not be slow to detect and let me ask you to accept my assurance that they are not due to any want of appreciation on my part of the importance of the task which has been entrusted to me.

Our first consideration must be what is understood by the term "myelitis." It should mean an inflammation of the spinal cord and in all cases of the kind there should be definite changes of an inflammatory character in the cord. The term "myelitis" has been applied to a malady which

apparently is very common, for both in hospital and private practice we daily hear of instances of myelitis, and if we look up the text-books for information we find that myelitis, which is described as a comparatively common disease, occurs with considerable frequency. However, I venture to affirm that myelitis, if the term be strictly applied to an inflammation of the spinal cord, is in reality a rare malady. I am entirely in agreement with Dr. H. Charlton Bastian, whose views have not received the attention they deserved, that much of what is spoken of as myelitis is in reality a softening of the spinal cord consequent on vascular occlusion, in which inflammation plays no part except it be that some inflammatory process in connexion with the walls of the blood-vessels permits of the thrombosis or clotting which results in the cutting off of the blood-supply from some area of the cord, which results in the softening. When a patient falls a victim to hemiplegia as a result of occlusion of a vessel in the brain we speak of the hemiplegia as due to thrombosis with softening and we would not dream of applying the term encephalitis to the process. Indeed, we recognise that encephalitis is a comparatively rare malady. Nevertheless, when precisely the same process occurs in the spinal cord and leads to paraplegia we designate the condition myelitis instead of speaking of the affection as spinal thrombosis with softening. It may of course be comparatively easy to demonstrate thrombosis of a large vessel in the brain, whereas it is very difficult indeed to demonstrate this condition of things in the smaller vessels of the spinal cord. This is one of the reasons why it is difficult to alter the old conception that the condition is a myelitis or inflammation, whereas it is in reality a softening in the cord due to thrombosis.

Let me first call your attention to the difference in the morbid process in the spinal cord in the inflammatory cases as contrasted with those in which there is softening consequent on vascular occlusion, after which I must refer to one or two points of difference in the clinical pictures of the two classes of case. The slides which I shall now throw on the screen are from a case which I studied in conjunction with Dr. Howard H. Tooth, one of my colleagues at the National Hospital for the Paralyzed and Epileptic. The changes which were present in the case were identical with those which were found in another case which I had the privilege of studying in conjunction with Dr. Thomas Buzzard of the same hospital. The first slide represents a section from the thoracic region of the spinal cord and the destructive effects of the inflammation are abundantly evident in various parts of the section, notably in the ventral aspect of the cord. The ventral horn on one side is considerably affected, together with the ventral portion of the white matter, while on the other side similar changes are seen, though they are less pronounced. The blood-vessels are engorged and small extravasations of blood are seen in different parts. The dorsal aspect of the cord is not so much affected as the ventral and lateral parts in this case. The next section is from the cervical cord, and the chief morbid changes are in the ventral aspect of the cord generally, including the ventral horns, and there is some affection of the lateral region, but the dorsal portion has largely escaped. Another section from the cervical cord shows even greater damage. The ventral horn is completely destroyed by the inflammatory process, and there is a great deal of inflammation evident in various parts, including the region immediately behind the commissure. The next sections represent higher magnifications of the same regions of the cord to show that the process is truly of an inflammatory character. The round cell infiltration, engorgement of vessels, and in many places actual hæmorrhages are well seen. This condition, which may be legitimately regarded as an acute inflammation, and which is present in some cases, is, I maintain, a rare affection. In contrast to this let me show you what obtains when there is occlusion of spinal vessels leading to softening of the cord. This is a common condition and is generally incorrectly spoken of as a transverse myelitis. I am indebted to Dr. W. Gordon Holmes, the pathologist of the National Hospital for the Paralyzed and Epileptic, for his kindness in preparing these sections, the first of which is from the mid-thoracic region of the cord where these lesions are most commonly situated. There is softening of the cord more marked on one side than on the other and due to vascular occlusion. In contrast to the other case to which I directed your attention you can determine by tracing the sections up and down the spinal cord that the morbid process is in reality limited to only a few

segments of the cord, and that in other regions ascending and descending degenerations can alone be detected as secondary consequences of the destructive lesion in the mid-thoracic region. There is not, as in the other case, an inflammatory process which has spread throughout the cord. The next slide shows the condition immediately above the chief seat of the lesion. There is still some softening evident at this level of the cord in addition to the changes due to ascending degeneration of the afferent tracts. Goll's column is completely degenerated but Burdach's column is only affected in part as healthy nerve roots have passed into this tract above the level of the lesion. In the lateral aspect of the cord degeneration is seen in the dorsal and ventral cerebellar tracts. At higher levels of the cord, as we gradually pass away from the area of softening, the degeneration becomes more strictly confined to the ascending tracts, the posterior columns, and cerebellar tracts, and no softening or degeneration is to be seen in other regions of the transverse area of the cord. Below the level of the lesion we find the posterior columns are intact but there is degeneration of the lateral or crossed pyramidal tracts and certain ventral tracts which degenerate in an efferent direction, including the direct pyramidal tracts. At a still lower level of the cord the lateral columns reveal the chief amount of degeneration and although slight degenerative changes are still evident in the ventral tracts no other parts of the transverse area of the cord are affected by softening or degeneration. This class of case is the most common, but although the condition is spoken of as myelitis it is in reality a softening of the cord and not an inflammatory affection such as I first showed you cases of, which are rare.

The time at my disposal will not allow of my saying much in regard to the differences in the clinical pictures of these cases. In the last class of case, in which there is softening of the cord consequent on occlusion of vessels, the onset is often sudden without premonition; it may be even as sudden as in hæmorrhage into the cord, but such cases differ from hæmorrhage in the fact that in them there is much less liability to pain at the onset of the attack. A patient of the kind rapidly loses power and is found to be paralysed in the lower limbs and the lower part of the trunk, and sensibility is affected in the same regions. In contrast to this, in the cases of acute inflammation the patient experiences some premonitory symptoms which point clearly to the existence of a febrile malady. There are a feeling of general malaise, headache, and perhaps rigors, which symptoms are followed by subjective sensations in different parts, notably in the lower limbs, which become progressively weaker until the paralysis ultimately reaches the trunk. It may be arrested there or the process may extend higher until death results from paralysis of the muscles of respiration. There is therefore not the same limitation of the paralysis, as a rule, in the way that usually obtains in cases of softening, in addition to the fact that it is not so abrupt in its incidence. There is much less likelihood of an abrupt onset of paralysis without premonition in the inflammatory cases.

I next wish to direct your attention to the disease which is described as poliomyelitis, acute anterior poliomyelitis, otherwise known as infantile paralysis. From the point of view of scientific accuracy it is well for us to examine our position in regard to this variety of myelitis in the same way that we have done with regard to the other form of myelitis. Different views are held as to the pathology of this affection as in the case of that which we have just discussed. There are authorities who maintain that this condition, like the other, is a true inflammation of the spinal cord. Others, however, hold that the condition is in reality the result of thrombosis which leads to occlusion of vessels. My colleague, Dr. F. E. Batten, in a paper recently published in *Brain*, has recorded three cases of poliomyelitis, and owing to his kindness I am able to show you slides from sections of the cord of one of these patients, reproductions of which sections will be found in his paper. The sections show a process of softening in the ventral horns of the cord, which lesion exists on both sides, although it is more marked on one side. It is not often that we have an opportunity of seeing sections of this kind, so that I am specially indebted to my colleague for supplying me with the slides which I am showing you this evening. I am also glad to be able to show you these sections because they enable me to justify the view as to the pathology of the affection which Dr. Batten supports in his paper. He holds, I think with considerable justification, that the changes met with in the

spinal cord in cases of poliomyelitis may legitimately be regarded as due to vascular occlusion rather than as the outcome of an acute inflammation. He is able to show three different stages of the affection in his paper: the acute stage, in which round cells are seen in conjunction with small hæmorrhages and engorged vessels, a stage in which there is softening, and a stage in which sclerosis results, with atrophy of the horn in the most long-standing cases, in which death results years after the actual lesion. He calls attention to the fact that the process is absolutely limited to the region of supply of the branches of the anterior spinal artery, a fact to which Williamson called attention some time ago in a paper dealing with the distribution of spinal vessels and lesions which result when they are affected. The branches of the anterior spinal artery supply the grey matter of the ventral horns and the morbid process in anterior poliomyelitis is limited to the region of supply of these vessels, so that occlusion of branches of the anterior spinal artery would adequately explain the condition of things met with in the disease. In contra-distinction to this there are those who hold that the condition is inflammatory, and Head and Campbell as a result of their researches on the subject have been led to the conclusion that the morbid process is unquestionably inflammatory and not thrombotic. In support of their argument they advance the fact that Mott, in his investigations on the brains of monkeys in which Leonard Hill had ligatured the carotid arteries, was only able to find evidence of chromatolysis of the cells of the brain without evidence of acute inflammation. There was no evidence of engorgement of vessels, round cell infiltration, and hæmorrhagic extravasations such as result in acute inflammatory processes. Dr. Batten, however, points out that the process which results in connexion with the occlusion of a large vessel like the carotid, is scarcely applicable to what may be found as a consequence of occlusion of small vessels, so that blocking of minute capillaries may lead to a condition of things which is quite different to what is met with when a large vessel is occluded. He cites the experiments of Prévost and Cotard, in which these observers, by injecting fine tobacco seeds, were able to produce infarcts in various organs, and congestion, exudation of cells, and hæmorrhages were the early results of the obliteration of small vessels in precisely the same way that these are seen in the earliest stage of acute anterior poliomyelitis. There is thus much to be said in support of the view that Dr. Batten has advocated and which is in accord with the view that Dr. Bastian has advanced to explain much of what is spoken of as myelitis. There seems little doubt that many of these conditions are due to occlusion of vessels rather than to an acute inflammation.

In addition to the arguments which I have already advanced on the subject there is another on which Dr. Batten lays stress—namely, that poliomyelitis is much more commonly met with in the lumbar region of the cord than elsewhere and that the lumbar region is the part whose blood stream is most remote from the heart, while the reinforcing arteries of the spinal roots which supply this region of the cord have a much longer course than elsewhere. So that it is from both standpoints a region of the cord in which thrombosis would be likely to result. In addition to these arguments I must add that the abruptness of onset of the paralysis in many cases of anterior poliomyelitis is another reason why a vascular lesion may reasonably be regarded as the cause rather than a slower inflammatory process. Although we are obviously dealing with a febrile malady in which it may be reasonably supposed that an infective agent is responsible the facts, both clinical and pathological, far better accord with some infective process which leads to affection of the walls of the blood-vessels and that in consequence they become occluded by clot which results in the paralysis rather than that the infective agent is responsible for causing an actual inflammation in the spinal elements as distinct from thrombotic softening the result of inflammatory changes in the walls of the vessels. It is, to my mind, difficult to understand why an inflammatory process should so absolutely limit itself to one region of the cord in the way it does in poliomyelitis. Inflammatory processes such as I had the opportunity of demonstrating in the first slides I showed you this evening do not, as a rule, permit themselves to be bound in by such limitations as are seen in poliomyelitis; they spread irregularly and are not limited to any one region in which they happen to begin. Inflammation is most common in the most vascular regions it is quite true, so that as the grey matter is more vascular than the white it is only as reasonable to expect more changes in the grey, but that

the changes should be so limited to the grey matter as they are in poliomyelitis makes it difficult to accept the view that they are inflammatory. Happily for me, I see no eye fixed upon me fortified by a monocle or I should scarcely dare to tell you that chronic myelitis is a myth for fear that I might be branded with a monosyllable whose synonym has been expressed as "a terminological inexactitude" in another assembly. I am, of course, familiar with acute myelitis which does not get well and which leaves behind it a chronic condition of things which remains with the patient for years and when the patient dies a chronic process is found in the spinal cord. That chronic process, however, is the remains of an acute condition in the past. I am also familiar with cases of compression of the spinal cord in which a slow softening results in connexion with a progressive inflammatory change. In some of these cases there undoubtedly is an extension of inflammation from the cause of the compression in addition to interference with the vascular supply of the part compressed. So that both a process of inflammation and one of softening consequent on thrombosis account for the clinical picture. Again, I am familiar with the cases in which meningo-myelitis occurs, of slow progress, where an inflammatory process commencing in the membranes of the spinal cord leads secondarily to inflammation in the cord itself. A process of this kind may be, of course, slow in its progress and may be due in part to extension of inflammation and in part to interference with the vascular supply of the cord. Furthermore, I am of course familiar with the effects of syphilis on the spinal cord, in which the syphilitic process occasions slow and progressive changes in the cord. But in syphilitic cases even the process is largely vascular and the main effect is an endarteritis with thrombosis or, if not actual thrombosis, interference with the vascular supply of the cord. It is to none of these cases that I refer when I say that chronic myelitis is a myth but to cases in which it is said that a slow progressive inflammation of the spinal cord may result as a primary affection and in which injury, exposure to cold, the rheumatic or the gouty states, and similar causes are said to be capable of starting an interstitial inflammation in the connective tissue of the cord, which slowly progresses and causes damage to the spinal nerve elements, which leads to a slow but progressive paralysis which may ultimately lead to the death of the patient. We are told by those who have written on the subject of chronic myelitis that the condition is one which may be induced by the same causes as are capable of producing an acute myelitis, so that the same causes acting over a longer period of time in lesser degree may set up a process of chronic inflammation in the cord. It is with this form of chronic myelitis that I entirely disagree. I am familiar with the various forms of myelitis to which I have already referred, but I do not agree with the view that there is a form of chronic myelitis such as I have just described.

If I succeed in doing nothing more this evening than inducing everyone in this room to look with suspicion on any case that appears to be chronic myelitis in future I shall be satisfied that my efforts have not been in vain, for I know that by so doing I shall be instrumental in rescuing not a few patients from a state of permanent paralysis which might be cured if a diagnosis other than chronic myelitis were made. How, then, are we to explain or to account for cases that have been regarded as chronic myelitis in the past? There are many conditions that claim cases that have been so regarded. Let me show you lantern slides of one or two conditions that have undoubtedly been mistaken for chronic myelitis in the past, though with our increased knowledge of these diseases they are now correctly diagnosed. The first condition to which I wish to refer is disseminated sclerosis. There is no doubt that the spinal form of disseminated sclerosis accounts for many cases that hitherto were regarded as examples of chronic myelitis. You find in the spinal form of this affection a slowly progressive paralysis of the lower limbs in exactly the same way as we have been told that the paralysis occurs in chronic myelitis and this malady may go on for many years limited to the spinal cord in this way, and in consequence an erroneous diagnosis is made. This section which I now exhibit is from the cervical region of the cord and shows that a considerable portion of the white matter in the ventral part of the cord has escaped degeneration, as has the grey matter. The next section shown is from the thoracic cord and reveals a more extensive involvement, so that but little of the white matter

has escaped, and you can readily understand how such an affection of nearly the whole transverse area of the cord would lead to paraplegia in the same way as if a myelitic process had affected the same transverse area of the cord. Here is another section lower down in the thoracic region abutting on the lumbar in which we have a less extensive affection of the white matter of the cord by sclerosis, whereas a section from the sacral region shows that the whole of the transverse area of the cord is affected. The nerve roots are, of course, undegenerate, which proves that in this disease, although the process is so diffuse, the grey matter escapes in great measure. The ventral horn cells do not undergo degeneration to any extent and in consequence the ventral roots escape degeneration.

Another malady which probably has accounted for mistakes in diagnosis in the past is the disease of which I now show you slides and for which we have no short name, so that for want of a better it has been called subacute combined degeneration of the cord. This is the best name we could formulate for the condition in a paper published in conjunction with my colleagues Dr. Batten and Dr. J. S. Collier of the National Hospital for the Paralyzed and Epileptic. This disease is another in which a slowly progressive paraplegia results and all the manifestations from the point of view of the paraplegia are such as would accord with the descriptions of chronic myelitis in the past. There are certain distinctive features in the clinical picture of these cases but time will not permit me to go into these details this evening. The sections show that in the cervical region there is only a little degenerative change in the white matter of the ventral region and that the main degeneration is in the posterior or dorsal tracts and in the lateral columns of the cord, including the cerebellar as well as the pyramidal tracts. In the thoracic region there is much more extensive affection and nearly all the white matter has undergone degeneration except that which immediately abuts on the grey. Otherwise there is extensive degeneration throughout the transverse section of the cord—a condition of things which you will remember closely simulates the appearance which you saw in the case of softening of the cord, the result of vascular occlusion, which is commonly regarded as a transverse myelitis. You can thus readily understand how a paraplegia may result from a lesion of this kind in the spinal cord in the same way that paraplegia has been supposed to result from chronic myelitis. A section from the sacral region shows that there is still some degeneration of the pyramidal tracts, merely a descending degeneration, and that otherwise the section of the cord is fairly free from any degenerative change. The process of degeneration is accordingly most pronounced in the thoracic cord, though it affects other regions and leads to secondary ascending and descending degenerations as would result from myelitis, and to a form of paraplegia that may well have been regarded as due to chronic myelitis.

It is not, however, to either disseminated sclerosis or this affection that I especially wish to direct your attention this evening in dealing with the importance of a correct diagnosis when chronic myelitis is supposed to be present, because, unfortunately, no treatment that we know of can influence materially the clinical course of either of the two diseases to which your attention has been called. It is the possibility of tumour of the spinal cord that I particularly beg you to have in mind when you are presented with a case that suggests that chronic myelitis accounts for the clinical picture. There are, of course, tumours of the cord which are inoperable, as evidenced by this section of an intramedullary tumour, with the cord surrounding the growth. I do not suggest that a correct diagnosis in such a case as this would place the patient in any better position than if a chronic myelitis were diagnosed, as an intramedullary tumour of this kind is, of course, beyond the possibility of aid from the surgeon. This other tumour, although it has destroyed only half the cord, would not permit of operative interference that would materially assist the patient. It is rather to those cases in which tumours grow outside the cord and compress it that I would call your attention. A tumour of that kind growing from the theca or from a nerve-root and compressing the cord in this way is a tumour which lends itself to operative intervention, and a tumour growing in this way may produce a clinical picture which may simulate that which has been described by the older writers as characteristic of chronic myelitis. I cannot better impress you that what I have

said in regard to tumours of the cord simulating chronic myelitis and chronic myelitis being diagnosed where tumour really exists is no exaggeration than by quoting the following case which was rescued from a "home for incurables" by my present house physician, Mr. H. Morrison Davies. The patient was a woman aged 55 years. She was single [and was admitted into University College Hospital under my care complaining of loss of power in both legs. This condition commenced with feelings of numbness in her feet in December, 1904, and the weakness in her legs first commenced in May, 1905. The weakness continued for a time and then she apparently recovered and was able to get about. But she relapsed afterwards, and at the end of a month after her relapse she began to have some difficulty in passing her urine, so that retention resulted. Throughout the whole course of her illness up to that time she had had no pain in her back and no radiating pain in her limbs, no girdle sensation or anything of the kind which might be expected from a tumour growing outside the cord and pressing upon it. This shows that there need not necessarily be pain in cases of tumour of the cord and that thus a tumour may come more closely to simulate what is expected in chronic myelitis. Later in her clinical history she complained of some pain, shooting up from her feet to the knees, but never up to the time I saw her had she had any pain in her back or any girdle sensation or pain radiating into the limbs. She, however, complained of pain in the gastric region six months or so before she came under my observation, and this proved to be due to a gastric ulcer. She had vomited and subsequently hæmatemesis occurred. The ulcer, however, healed under rest and appropriate treatment. When she came under my observation she had very marked spastic paraplegia with anæsthesia, the knee-jerks were exaggerated, there was ankle clonus, and the plantar reflex was of the extensor type. The limbs were wasted generally but there was no obvious wasting of any definite groups of muscles. The skin was dry and harsh and she had a sacral bed sore. In discussing the case with the students I pointed out how the condition might quite well accord with what had been described as chronic myelitis and also how the diseases disseminated sclerosis and subacute combined degeneration of the cord might account for the morbid picture which, for various reasons, we concluded was due to a tumour compressing the cord. The patient was submitted to my colleague Sir Victor Horsley who performed laminectomy. A tumour of the size of a filbert was found on opening the theca after removing the sixth and seventh thoracic spines. The eighth had also to be removed in order to free the lower edge of the tumour and it was elevated from its bed and the patient is making a satisfactory recovery. This, remember, in a patient who was in a place where she would have remained paraplegic for the rest of her days if she had not been accidentally discovered.

Time will not permit me to multiply examples of this kind, but in justice to chronic myelitis it is only fair that I should say that it is not the only condition, hypothetical or otherwise, that has been responsible for claiming cases that are in reality examples of tumour of the spinal cord, and, further, that cases may appear to be due to tumour which, while not due to chronic myelitis, are due to a form of chronic meningitis about which I can tell you very little. Only one case of the kind has come under my observation—where I diagnosed tumour in a woman and recommended operation and where the patient was operated on by Sir Victor Horsley. No tumour was found but a condition of chronic meningitis existed. Sir Victor Horsley tells me he has had a considerable experience of this kind of case but it is the only instance I have seen and I confess that I do not at present see how such cases are to be diagnosed correctly from cases of tumour of the cord. Sir Victor Horsley has promised to place his cases on record, so that we must look forward to his paper for further information on this important subject.

I cannot conclude without a word or two in regard to prognosis and treatment in myelitis. The point I wish to make clear in regard to prognosis is, how uncertain this is in these cases. Patients who are seemingly in a hopeless condition from myelitis may get well under appropriate treatment. I should like in this connexion to quote, if you will allow me, two cases. One is the case of a young man, who was seen in consultation with a medical man who is present this evening. He was aged 18 years and had never been in the way of contracting specific disease and there was no evidence about him whatever of syphilis. From a

vague state of ill-health he fell into a condition of paraplegia which was so severe that one of our best authorities on nervous diseases who saw the patient gave a most unfavourable prognosis. The patient, however, subsequently, under careful treatment, made an uninterrupted recovery and is now completely well. So that whereas at the outset he had all the evidences of an acute infective process, including a scarlatiniform rash and acute cystitis in association with paralysis of his sphincters, he made a recovery so complete that now, up to the last time anything was heard of him, and when he passed from observation, even his bladder had completely recovered. Another case which I would like to quote is that of a man, aged 24 years, who was admitted into University College Hospital under my care. He developed a paraplegia which was gradual in its onset, taking about two days in all to reach its maximum, and the condition being preceded by pain in the back and general feelings of malaise for about 24 hours antecedent to the first manifestations of his paraplegia. This man had paraplegia so severe that his limbs were absolutely flaccid, his knee-jerks had disappeared, as had the ankle-jerks and the plantar reflexes. He had severe burns on his feet from hot-water bottles before he was admitted into the hospital, a sacral bed sore, and cystitis. He denied specific disease and no evidence of syphilis could be determined. His condition was about as bad as it was possible to imagine in any case of myelitis, and yet under careful treatment he, like the lad to whom I have just referred, made a steady and uninterrupted recovery, so that now he is able to walk perfectly well and has completely recovered the functions of his bladder.

At this late hour in the evening I do not propose to detain you longer than just to advocate one measure of treatment in myelitis. Irrespectively of whether the patient be suffering from syphilis or no, I am convinced that there is no treatment that can compare with mercury and that mercury rubbed in is to be preferred to mercury given by the mouth. Mercurial injections, of course, in acute cases where the disease is rapidly spreading are highly desirable. But in ordinary cases where we have time to treat our patients more deliberately mercury by means of inunction is especially to be recommended. In all the cases I have anything to do with where we are dealing with myelitis I never fail to recommend this measure in treatment and I share Sir Victor Horsley's belief in the value of local inunction. Whether mercury is rubbed into other parts or not it should certainly be rubbed along the spinal column. In all the cases with which I have had to deal this mode of mercurial treatment has been adopted. It was so in both of the successful cases to which reference has been made, in neither of which could any evidence of syphilis be obtained.

A Lecture

ON

TUBERCULOSIS OF THE CÆCUM, ILEO-CÆCAL VALVE, AND APPENDIX,

WITH FOUR UNPUBLISHED CASES.

Delivered at the Medical Graduates' College and Polytechnic, London, on May 14th, 1906,

By C. B. KEETLEY, F.R.C.S. ENG.,

SENIOR SURGEON TO THE WEST LONDON HOSPITAL.

GENTLEMEN,—When tuberculosis of the intestine forms a solitary well-marked tumour the ileo-cæcal valve or the cæcum is usually the part affected and the tumour is therefore in or near the right iliac fossa. Tubercle of the rectum is not uncommon but usually leads to ulceration and fistula rather than to tumour. It is not that the process in the two localities is essentially different. If we felt ileo-cæcal or appendical tuberculosis from within we should often call it an ulcer; if we felt rectal tuberculosis from without we might describe it as a tumour. These forms of tuberculosis of intestine must be distinguished from the often extensive ulcerations which complicate the last stage of pulmonary tuberculosis. Tubercle of the appendix is said to be nearly always secondary to disease of the cæcum but it is

possible that it is sometimes primary and overlooked owing to ulcers of the appendix not always being examined with a view to their precise bacteriological origin. In the cases which I am going to describe the dominant factor was the disease of the ileo-cæcal valve and of the cæcum. In what proportion of cases cæcal tuberculosis is secondary to infection elsewhere, especially of the lungs, is still unsettled. Even when pulmonary tuberculosis co-exists it does not necessarily follow that the cæcal trouble is truly secondary to that of the lung. The two parts of the intestinal canal which above all others we should expect to be liable to be infected from bacteria in food and its products are the ileo-cæcal region and the rectum. Because there fæces lodge and time is given for bacteria to penetrate.

Ileo-cæcal and appendical tuberculosis may be ulcerative, or hyperplastic, or peritoneal. Even in the ulcerative variety there is usually some thickening accompanied by congestion and a tendency to form adhesions. On opening the appendix, if that organ be affected ulceration is seen, often visibly caseous. The tubercles affect every layer of the wall, submucous, muscular, and even serous occasionally, as well as mucous. But the mucous and submucous layers are affected most. Similar changes are observed in the cæcum when that is diseased. In my own cases a small abscess lay between the appendix and Poupart's ligament in one and in another the meso-cæcal glands were extensively affected (full of almost fluid cheesy matter) and the meso-cæcum itself enormously thickened (hyperplastic). The essential feature of the hyperplastic variety of intestinal tuberculosis is the thickening, often very great, of the organ, mainly due to connective-tissue proliferation in the submucous layer. It is this, combined with the thickened meso-cæcum and its contained glands, and occasionally with a small abscess, which produces the palpable tumour. A part of the appendix often escapes even when the rest is seriously affected. Bouglé, quoted by Battle and Corner, says that the base of the appendix rather than the tip is affected, the contiguous part of the cæcum often being involved. "Hence it is close to the cæcum that perforation of tuberculous ulcers is most likely to occur."

The symptoms of tubercle in the region of the appendix and cæcum are mainly those of chronic or of subacute inflammation. When the cæcum is not involved the usual diagnosis is that of chronic appendicitis. When the cæcum is also affected and when, owing to hyperplasia, a tumour can be felt, and especially in the common case of the patient's not being young, malignant disease is often suspected. With either tuberculous or carcinomatous ulceration of the ileo-cæcal valve blood and mucus may occasionally appear in the stools; irregularity of the bowels, either constipation or diarrhoea, may occur; and tubercle bacilli may not be found in the stools even if the disease be tubercle, especially if it affects the appendix only. With either tuberculous or carcinomatous disease of the cæcum great wasting occurs. My elderly patient was reduced to a weight of less than five stones. But however ill my tuberculous patients were they had not the facial aspect of sufferers from cancer. On the contrary, they had the delicacy of tuberculosis, its thin, smooth skin, long eyelashes, and bright eyes. The history of the patient, and in a less degree that of his family, may be significant. Nevertheless, the actual diagnosis is only made by operation.

A graphically reported case which illustrates some of the above-mentioned points was published in THE LANCET by Mr. H. W. Page.¹ A woman, aged 36 years, in St. Mary's Hospital, had suffered from abdominal discomfort, more or less, for 18 months. Nine months before admission she had an attack of pain in the right iliac fossa accompanied by vomiting and constipation. Attacks of the same kind, two or three in number, but of less severity followed at intervals, and in one which occurred shortly before her coming to the hospital a distinct lump had been felt in the iliac region. Now, under anaesthesia, "a small, hardish lump" was still felt in the cæcal region. With dieting and rest in bed the pain was relieved and the patient was prepared for an appendicectomy. It should be, and was, noted that the patient was pale and emaciated and showed the scars of glandular ulceration in the neck. Laparotomy discovered a healthy appendix and a tumour of the cæcum as large as a hen's egg, bound by firm adhesions both to the abdominal wall and to the iliac fossa. This was nine years ago and it is therefore not surprising that the removal of the

tumour was not attempted. After this patient's death an exhaustive necropsy by Dr. F. J. Poynton showed a cæcum much ulcerated and thickened by chronic inflammation and an ileo-cæcal stricture half an inch in length of almost cartilaginous hardness and only admitting the passage of a probe, extensive ulceration on the cæcal side of the stricture, and perforation "at a point contiguous to it." From this perforation the patient had died. No ulceration was found elsewhere but in front of the duodenum was a caseous gland of the size of a small orange and there was an old scar just below the apex of the right lung. Microscopically "the bowel showed chronic inflammation without sign of either sarcomatous or carcinomatous growth and although not definitely tuberculous it was almost certainly of this nature."

Here we have exemplified the tumour in the right iliac fossa, rather small, rather hard, and chronic in comparison with that caused by ordinary appendical or perityphlitic abscess; the long history of abdominal discomfort with occasional acute attacks, the well marked loss of weight, and the suspicion of malignancy (in spite of the presence in this case of the scars of old tuberculous cervical glands), the laparotomy and the closure of the abdomen without removing the growth, the death (in this instance from perforation), and, finally, the post-mortem appearances as just given. I believe that scores of surgeons could each relate from his own practice a case with a close resemblance to the above.

In April, 1904, my friend, Dr. G. Sidney Shute of Gravesend, and I had a female under our care, unmarried, and aged about 60 years. Her personal history resembled that just given of the patient in St. Mary's Hospital. She was so emaciated that she had sunk in weight to between 4 and 5 stones! There was a small hard tumour in the cæcal region adherent to the iliac fossa and to the outer half of Poupart's ligament. On April 24th, assisted by Dr. Shute and Mr. G. W. Micklethwaite, I operated and found a small abscess with the appendix at the bottom of it. The ileo-cæcal junction was greatly thickened. Taking precautions to protect the general peritoneal cavity I therefore freed the whole mass of diseased intestine completely and bringing it outside the abdomen fixed it there, gauze-packing the abscess cavity. The next morning I opened the ileum, making a temporary artificial anus. The ileo-cæcal valve was almost impervious and much ulcerated. On May 27th I excised the cæcum and the ileo-cæcal valve and now found the peritoneal coat of the ileum studded with small tubercles. I fixed and left the ascending colon and the ileum, both open, side by side in the wound. For the next four months the fæces passed through the ileostomy, but the large intestine was kept well supplied with water. During this period the patient's general condition and good spirits improved enormously. She put on nearly 3 stones in weight. On Sept. 21st I performed enterorrhaphy by Maunsell's method and closed the wound. The patient has been well ever since. It should be mentioned that the peritoneal tubercles seen at the second laparotomy had all disappeared at the third—namely, in the period during which her fæces were passed through the ileostomy and during which she put on so much flesh. Both this case and the next show how the general nutrition can be not only kept up but greatly improved without the assistance of the large intestine except as an absorber of water.

In October, 1904, a girl, aged 16 years, was admitted into the West London Hospital with the diagnosis of chronic appendicitis. I had seen her a year before with Dr. T. Matheson Ness. She was then suffering from a subacute attack, with vomiting and abdominal pain and tenderness, mainly in the right iliac fossa. With rest and medical treatment she improved at that time. She had on coming into hospital a distinct tumour of considerable size, had lost flesh, and looked very delicate. At the operation on Oct. 14th, 1904, the appendix and ileo-cæcal valve were found much thickened but the greater part of the tumour was a meso-cæcum full of large, cheesy glands. The course pursued was similar to that in the preceding case. The ileostomy was left open for three months, during which the large intestine was well supplied with water. The patient put on flesh. Tubercles seen on the peritoneum at the earlier operation had disappeared before the final one. In this case the right Fallopian tube was diseased and adherent to the mass of intestinal and mesenteric disease. I removed it but left the ovary which appeared normal. This patient has had good health since but has been troubled a little with small subcutaneous abscesses due to unabsorbed sutures.

¹ THE LANCET, July 3rd, 1897, p. 10.

In the treatment of both these cases great care was taken to make it as much "open air" as the means at our command permitted. The elder patient had the advantage in this respect, as, being a private case, the windows could be opened without regard to anybody's welfare but her own, and she has also been able to make prolonged stays at the seaside. She has regained more vigorous health than the younger. Still the latter has done well and benefited by a stay at the Yarrow Home, Broadstairs. It is interesting to add that through the generosity and gratitude of friends of the younger patient the hospital in which she was treated has profited to the extent of £575, which illustrates what I should venture to state as an established fact that our hospitals are supported by their beds—i.e., by the work done in them. It is a pity that committees and secretaries are prone to be disposed to fritter away the earnings of the beds on bloated and abused out-patient departments.

A case of tubercle of the appendix and of the meso-cæcal glands.—The patient, aged 11 years, was admitted into West London Hospital on July 16th, 1901. On July 7th she had complained of great pain in the right groin which was very acute at times and had been more or less severe since. She had been subject to similar attacks off and on for the last two years. She had had measles and whooping-cough but not scarlet fever. The bowels were opened freely after a simple enema. The patient appeared to be a healthy, well-fed child with no marked abnormality of any kind. When asked to point out the seat of pain she placed her hand on the abdomen below, and a little to the right of, the umbilicus. The lungs and the heart appeared healthy and the resonance note of the abdomen was quite normal. On palpating a certain abnormal feeling of resistance could be felt over the region of the cæcum.

On July 19th an incision of about three inches was made along the right linea semilunaris. The cæcum was drawn out and the appendix was found to be bound down tightly to the gut by tuberculous adhesions. The appendix was excised and the stump was invaginated and stitched. A large tumour lying behind the peritoneal attachment of the cæcum was next cut into and a mass of curdy pus was evacuated. The cavity was then scraped and iodoform gauze packing was inserted. The cavity was then approximated to the operation opening and fastened by a few sutures to its edges. The gauze packing projected outside and the wound was partially closed. A few smaller glands in the mesentery were left untouched. On the 20th the wound was dressed and the iodoform packing was removed and fresh packing inserted. On the 22nd the wound was again dressed and fresh packing was inserted. There was slight pain at intervals. On the 23rd the bowels were moved slightly and there was some pain. On the 24th the patient was very restless. She complained of pain in the lower bowel. Rectal examination showed masses of scybala. A simple enema gave relief. The wound was again dressed on the 25th. The patient had had a comfortable day and she slept at night. She was discharged from hospital on August 22nd, the wound having quite healed (34 days after the operation). The temperature, 100° F. on admission, never once rose above 99° after the operation.

Now, with regard to tuberculosis confined to the peritoneal coat of the cæcum and appendix. By chance I operated on a case of this description only yesterday (May 13th). A tall, well-made, and well-developed young woman, aged 19 years, is described as having been the picture of health till a year ago, when she began to be worried with recurrent abdominal pains, rather vague in situation but more in the right side than the left. Once appendicitis was diagnosed. Vague as they were these pains and illnesses were described as making life scarcely worth living. What was thought to be the appendix and ileo-cæcal valve could be felt by palpation and was tender. Her only brother had had appendicectomy performed. Her bowels were irregular, generally constipated. At the operation the incision was made over the appendix but I first through this incision palpated the gall-bladder. The appendix and the ovary felt normal though the former, as in her brother's case, was rather long. The cæcum was now pulled out. I examined the appendix, cæcum, meso-cæcum, and part of the ascending colon very carefully for abnormalities and especially for tubercles but noticing only one solitary suspicious and very minute nodule was going to give up the search when, turning the cæcum over, Dr. H. J. Davis, who was present, observed a colony of tubercles confined to the under or right side of that viscus. One tubercle only was

discoverable on the appendix itself near its base. The omentum and a coil of small intestine with its mesentery were now searched for tubercle with a negative result. The parietal peritoneum appeared quite free and no glands could be felt. The wall of the cæcum was perhaps a little thick. I removed the appendix, which when slit up showed a rather granular catarrhal condition of the mucous membrane. It had contained a small fecal concretion which I had slipped on into the cæcum while manipulating it. I did not feel called upon to remove this cæcum. The disease is in an exceedingly early stage, the patient is personally vigorous, and she is in a position to live an outdoor life and to stay at the seaside or in the country as long as may be desired. And it will be granted that serious operations for local manifestations of what may be a more generalised condition should be resorted to with discretion.

Those who wish to make acquaintance with anatomical and histological details of tuberculosis of the cæcum and appendix will find them fully and lucidly given, with admirable illustrations, in Dr. Howard Kelly's great work on the appendix.

A conviction which I published some years ago and have often expressed is that general tuberculous peritonitis often arises in tubercle of the cæcum or in the meso-cæcal glands, that whenever laparotomy is performed for that disease the cæcum, meso-cæcum, and appendix should if possible be examined, and, at least in males, the question should be entertained of incising in the right iliac region rather than in the median line. In females, of course, there is always the possibility of the primary focus being in the left uterine appendage. These views were brought forcibly home to me by a case in which I excised a small tumour from the cæcal region. It lay near the junction of the meso-cæcum with the ascending meso-colon and proved to be a bag of cheesy pus, so thin-walled that the slightest blow would have extravasated its contents into the peritoneal cavity, and the same views are supported by the cases just related. Further, these cases show that in dealing with this singular disease it is not too late to lock the stable door even when the horse is apparently stolen.

Lastly, I would point out that there might be a fair hope of curing ileo-cæcal and appendical tuberculosis without excising the disease, and merely by an ileostomy combined with suitable general treatment. I infer this from the good results I have seen ensue from treating extensive tuberculous ulceration of the rectum with fistulae, by simple scraping combined with an inguinal colotomy kept open until the tuberculous ulceration had thoroughly healed. But I think excision preferable. Whether an ileo-sigmoidostomy would prove curative or not is doubtful. After that operation fecal matter is not long before it finds its way back along the colon to the cæcum.

A MEANS OF CHECKING THE SPREAD OF "SLEEPING SICKNESS."¹

BY JOHN L. TODD, B.A., M.D., C.M. MCGILL,

DIRECTOR OF THE BUNCORN RESEARCH LABORATORIES OF THE LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

THIS paper has been drafted to indicate to those who have not followed the subject closely the wide distribution of human trypanosomiasis in Africa, to demonstrate the rapidity with which the disease is spreading, and to suggest measures intended to check further extensions.

Map 1 represents the distribution of sleeping sickness as known at present. The parasite causing the disease, the *Trypanosoma gambiense*, is ordinarily transmitted from infected to healthy persons by the bite of a tsetse fly, *Glossina palpalis*. We must therefore expect human trypanosomiasis to spread to the limits of the distribution of this fly. The northern and southern limits of the area in which *Glossina palpalis* has been found are indicated by dotted lines. Its actual distribution will certainly be found to be much wider. There are seven other varieties of tsetse flies and, until the contrary is proved, we must consider the

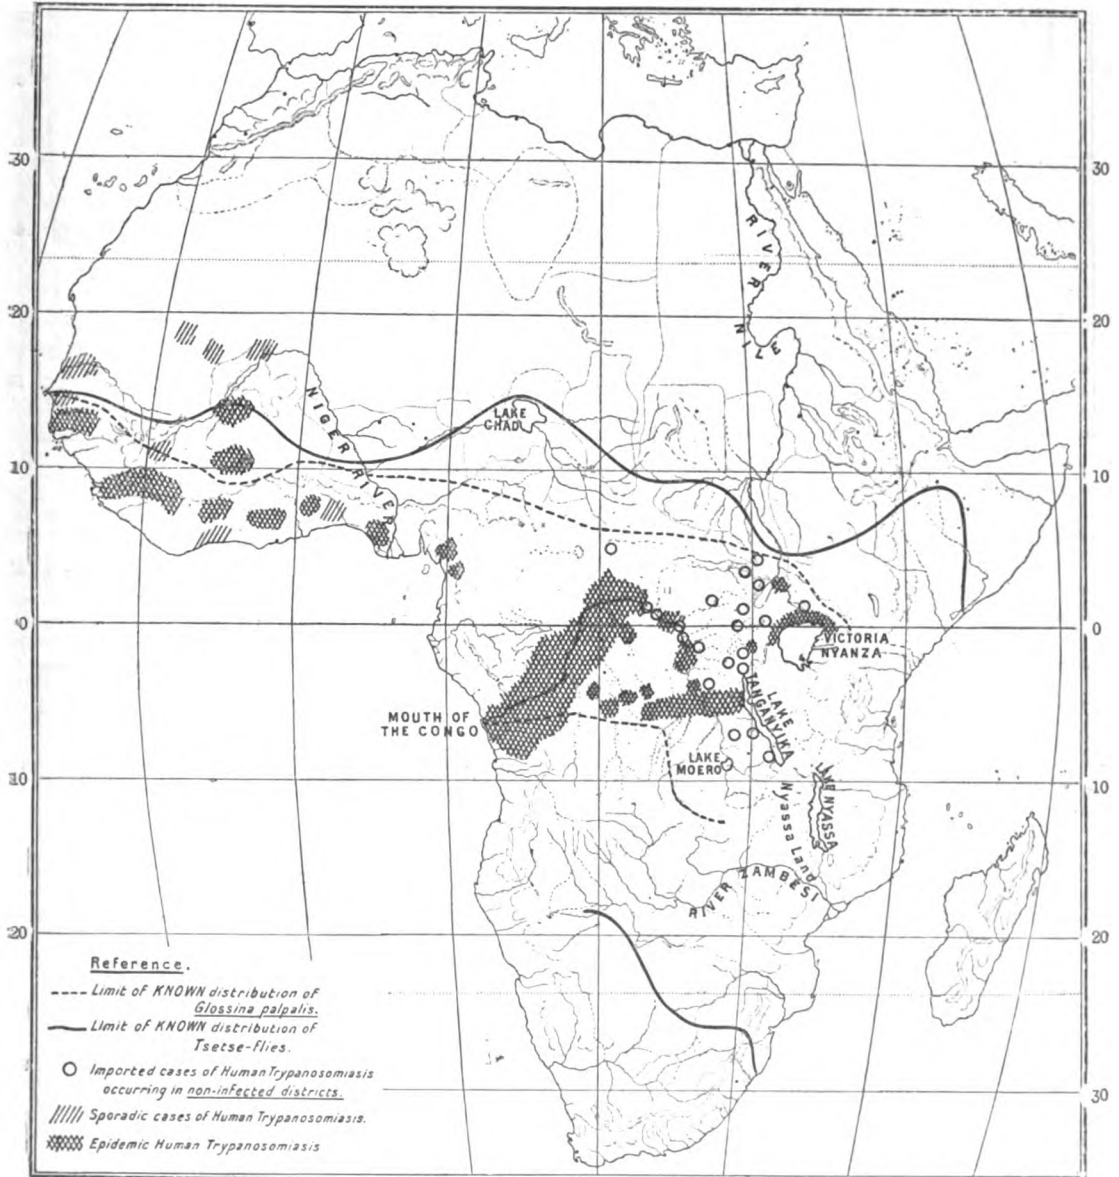

¹ For particulars of the observations and arguments on which this paper is based see Memor. XVIII., Liverpool School of Tropical Medicine, and the forthcoming volume of the Transactions of the Epidemiological Society, from which Maps 2 and 3 and many of the facts are taken.

possibility of each of them being also a carrier of the infection. The part of Africa within which tsetse flies are found is roughly limited by an uninterrupted line. In any case it is evident from an inspection of Map 1 that the uninfected areas of the Soudan, Northern Nigeria, German East Africa, British Central Africa, &c., are in the greatest danger of being infected.

The history of the various epidemics of human trypanosomiasis shows that it spreads but comparatively slowly from an infected area but that it may easily be carried, by the advent of an infected person, into localities where it did not

became easier and more rapid. Expeditions were sent in various directions to open up the country and military operations were commenced against the Arabs. These large undertakings involved an unprecedented movement of men—Natives—soldiers, workpeople, and their wives—were brought from infected districts to places previously free from the disease. In 1897, 12 years after the foundation of the Free State, cases of sleeping sickness were reported among the natives about Lulubourq and Lusambo (Map 2), places uninfected in 1884. The caravan routes between Lusambo and Kasongo were formerly much used. It was along

Known distribution of human trypanosomiasis and tsetse flies in Africa, 1905. Compiled from:—1. Laveran and Mesnil: Les Trypanosomes et les Trypanosomiasés, 1904. 2. Report No. VI. of the Sleeping Sickness Commission of the Royal Society. 3. Memoir XVIII. of the Liverpool School of Tropical Medicine.

previously exist. In the Congo Free State it is, for example, along the main routes of communication that the disease has spread. Two maps representing respectively the distribution of the disease in the Congo basin in 1897 and 1905 are annexed to demonstrate this point. Before Europeans entered the Congo basin sleeping sickness seems to have been confined to the region of the Lower Congo and to the banks of the main river as far up as Bumba (1884). No record can be obtained of its existence elsewhere. With the coming of the white men steamers were introduced on the rivers, caravan roads were opened up, and long distance transport

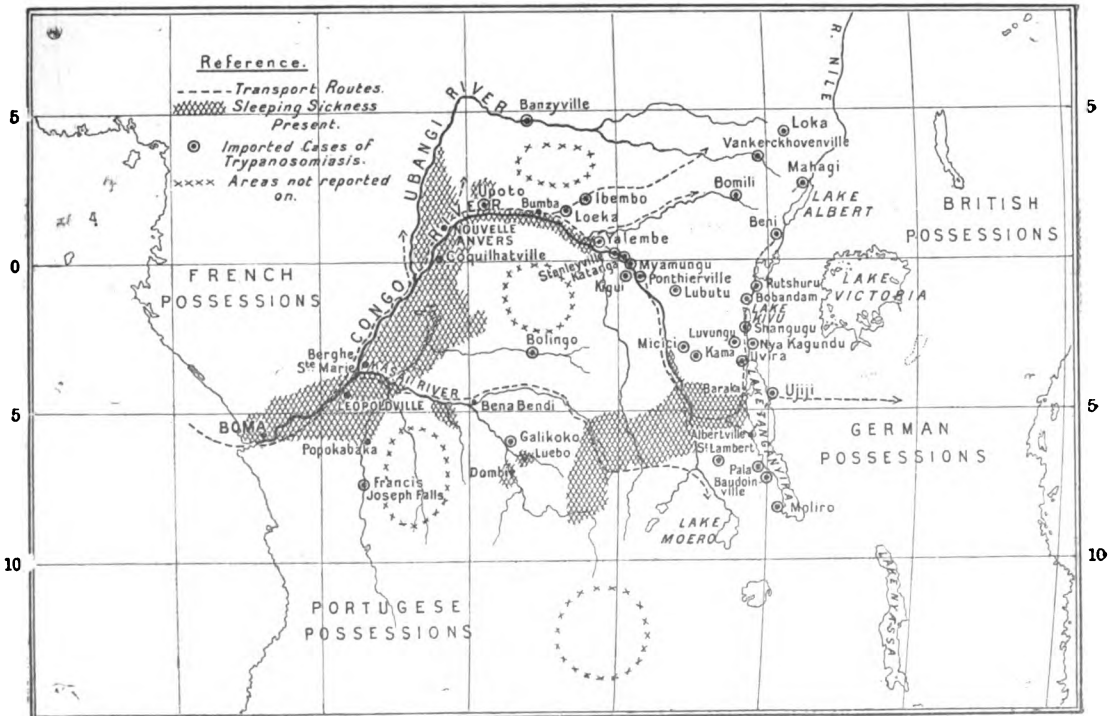

these routes that the troops directed against the Arabs advanced. Caravans carrying supplies to the posts in the eastern part of the Free State passed over the same roads which were also used by native and Arab traders. From Kasongo to Baraka and Albertville on Lake Tanganyika go very important caravan routes over which pass the whole of the supplies to the region about Lake Kivu and Lake Tanganyika north of 5° S. In 1896 the caravan route between Lusambo and Kasongo was closed and the transport between the east and west of the Free State went instead up the Congo in steamers to Stanleyville and thence

MAP 2.

Distribution of "sleeping sickness" in the Congo Free State, 1897.

MAP 3.

Distribution of "sleeping sickness" in the Congo Free State, 1905.

by canoes to Kasongo. Map 3 plainly shows the results of these movements. Sleeping sickness has spread along the most important overland routes and up and down the Congo from Kasongo until there are only comparatively small stretches of river between Stanleyville and Kasongo still uninfected. Posts in uninfected districts at which imported cases of sleeping sickness have been reported are indicated by circles. They give some idea of the frequency with which "clean" districts are exposed to infection. All these imported cases are soldiers, labourers, or their wives brought long distances from their homes as a direct result of the opening up of the country by Arabs and Europeans. It is evident that if such persons were removed from uninfected districts and if the ingress of others were prevented much would have been done to check the spread of human trypanosomiasis.

It is well known that negroes in the first stages of human trypanosomiasis are often apparently well, make no complaints, and work as effectively as any healthy individual. A means of detecting such cases has recently been devised. Enlarged lymphatic glands had long been observed to occur in cases of trypanosomiasis. Greig and Grey showed that trypanosomes could easily be found in the juice aspirated from such glands by means of a hypodermic syringe. By using this method we found in the Congo that in practice every negro whose neck glands are enlarged without obvious cause must be considered to be a case of trypanosomiasis until the contrary is proved. (This statement is based upon the examination of 6358 apparently healthy negroes of all ages and both sexes.) It is therefore proposed that good results may be expected from the serious application of quarantine measures directed against the advance of human trypanosomiasis and dependent for their efficiency upon cervical gland palpation.

The measures recommended are briefly: (1) the establishment of medical posts of inspection along the trade routes leading from infected to uninfected districts; and (2) the removal of infected persons from posts in uninfected districts to places already infected. If success is to be obtained the application of these measures must be thorough. The details of the way in which they are to be made effective cannot be considered here. They must be left to those who are to administer them. It may be suggested, however, that in most instances it will be impossible for the existing medical officers to enforce such measures in addition to performing their ordinary duties. The situation is quite serious enough to require the whole attention of special medical officers aided by competent staffs.

As an example of the applicability of the proposed measures consider the case of Nyassaland. It is certain (see Map 1) that the natives of the southern as well as of the northern shores of Lake Tanganyika will shortly be very heavily infected with trypanosomiasis. Labourers are engaged from the neighbourhood of Tanganyika to work in Nyassaland. There is constant communication between these two districts, since one of the most important caravan routes to Central Africa runs between Lake Nyassa and Lake Tanganyika. In my opinion, therefore, it is only a question of months before imported cases of the disease will be reported from Nyassaland. It is evident that the communication between these two areas should be stringently controlled. Posts of inspection should be established to prevent infected porters, in caravans, or labourers from entering British territory. Every employer of labour must be made to understand the danger of enlarged neck glands and should be instructed to send negroes possessing them to the nearest post of inspection. Each person residing or travelling in uninfected areas must be made personally responsible for the presence of persons with enlarged glands in his following. It is believed that the difficulties of applying these measures will not be as great as might be anticipated. Natives will soon learn and appreciate the danger of enlarged glands; they have long recognised their significance in Sierra Leone, Uganda, and in parts of the Congo Free State. It will admittedly be impossible altogether to control the movements of individuals, but it is not from single persons, as a rule travelling only a few miles, that danger is to be apprehended. It is the organised transport of groups of negroes which is dangerous.

It is concluded that: 1. The enormous spread and great increase of sleeping sickness in the Congo basin have been due in great measure to the increase in travel following the opening up of the country. 2. Cases of trypanosomiasis, though apparently healthy, may be detected by their enlarged glands. 3. We may expect to check the advance

of the disease by the serious application of quarantine measures dependent for their efficiency upon cervical gland palpation.

Addendum.—Since this paper was written apparently trustworthy reports have appeared in the daily press asserting that sleeping sickness has already appeared among the natives inhabiting the western shores of Lake Moero. The disease is spreading rapidly towards British Central Africa. The need for action is immediate.

Runcorn.

A NOTE ON THE ACTION OF THE SERUM OF VARIOUS MAMMALS ON THE BACILLUS PESTIS.

BY GEORGE LAMB, M.D. GLASG.,
CAPTAIN, I.M.S.;

AND

W. H. C. FORSTER, M.B., C.M. EDIN., D.P.H. CANTAB.,
CAPTAIN, I.M.S.

THE etiology of plague offers the bacteriologist many interesting problems for solution. Of these problems one of great general interest is the immunity enjoyed by some members of the order of mammalia under natural and artificial conditions of infection.

The Indian Plague Commission found that rats, mice, squirrels (Indian variety), and monkeys were all susceptible to the disease under natural conditions of infection and that there was proof of epidemics having occurred in the case of all these animals. Of these animals it was stated that the grey monkey (*Semnopithecus entellus*) was more susceptible than the brown monkey (*Macacus radiatus*). The cat was also found to be susceptible under natural conditions of infection, the disease running a chronic course and taking the form of buboes in the neck accompanied by wasting. Dogs, jackals, and birds apparently did not contract the disease in nature.

The finding of the German Commission after laboratory investigation was as follows:—Rats and guinea-pigs are very susceptible; mice are a little less susceptible; monkeys are nearly as susceptible as rats, the grey monkey being the most susceptible; cats are less susceptible. Dogs, pigs, oxen, sheep, and goats sicken after large doses but soon recover. On the whole they are little susceptible. Birds, snakes, lizards, and frogs are insusceptible.

Simpson and Hunter¹ claim to have succeeded in producing the disease by feeding upon material containing bacillus pestis several species of domestic animals and birds (pigs, cattle, hens, turkeys, ducks, geese, and pigeons). Since the publication of Simpson's results Pitchford in Natal and Bannerman in Bombay have been totally unable to reproduce them. Captain G. Liston, I.M.S.,² has recently shown that the guinea-pig when placed under natural conditions of infection readily contracts the disease.

So far as we are aware, the only mammals in India which have been definitely proved to be capable of contracting the disease under natural conditions of infection are rats, mice, squirrels, guinea-pigs, cats, and monkeys. These facts, we think, point to the desirability of a careful investigation of the action of the body fluids and formed elements of different animals of the order of mammalia on bacillus pestis. Up to date but little work has been done on unimmunised animals, and until we are acquainted with the action of normal serum, &c., on bacillus pestis the immunity of the larger mammals will remain unexplained.

Wright and Windsor,³ using methods of high precision, showed that normal human serum is devoid of bactericidal action on the bacillus pestis. The methods of these observers were as follows:—

1. Equal volumes of normal human serum and a graded series of dilutions of a broth culture of bacillus pestis were kept in contact for from 18 to 24 hours at 37° C. At the same time a parallel series was prepared consisting of equal volumes of sterile broth and the dilutions of the plague

¹ Simpson: A Treatise on Plague, p. 116, University Press, Cambridge.

² Indian Medical Gazette, February, 1906.

³ Journal of Hygiene, Oct. 1st, 1902.

culture. After incubation for from 18 to 24 hours the mixture of serum or broth and plague culture was drawn into broth and the two series were compared after further incubation. No appreciable bactericidal power could be discovered by this method.

2. An ascending series of dilutions of a plague culture were made on the one hand with serum and on the other with broth. Measured quantities of a 100,000 fold dilution of the culture made with broth were at once planted out on the surface of agar and the colonies were subsequently enumerated. From the corresponding dilution of the culture made with serum the same quantities were removed and incubated at 37° C. for from 18 to 24 hours, after which these quantities were sown out on the surface of agar and the colonies enumerated. No evidence of bactericidal action could be obtained by this method.

3 Normal serum was saturated with a dense suspension of bacillus pestis, and the bactericidal power of the serum for cholera and typhoid fever was tested. It was found that bacillus pestis was incapable of exerting an anti-bactericidal action.

Our original intention was to estimate the bactericidal and opsonic action of the sera of domestic animals for bacillus pestis before and after immunisation, but the formation of a new Plague Commission and the appointment of one of us to the same have rendered the completion of our intention impossible. We have therefore decided to publish our results as far as we have gone for the benefit of those who may be working in the same field. With this introduction we may pass on to a statement of the technique employed and the results obtained.

TECHNIQUE.

1. *Collection and storage of serum.*—(a) *Goat, ox, dog, horse, and sheep.*—In the case of these animals the blood was drawn from the external jugular vein by means of a sterile hypodermic syringe and allowed to clot in a sterile conical vessel.

(b) *Man and monkey.*—The blood was collected and allowed to clot in Wright's capsules. The part from which the blood was taken was first sterilised by scrubbing with a saturated solution of perchloride of mercury which was afterwards washed off by successive applications of absolute alcohol, ether, and sterile distilled water.

(c) *Rabbit.*—One ear of the rabbit was shaved and then sterilised by successive applications of a saturated solution of perchloride of mercury, absolute alcohol, ether, and distilled water. The animal was then strapped on a hot-water bag and the lateral auricular vein was clipped with a pair of bull-dog forceps near the base of the ear. A longitudinal cut was made into the distended vein and the blood was allowed to drip into a sterile conical vessel. By this method it was found that 10 cubic centimetres of blood could be obtained with ease.

(d) *Guinea-pig and rat.*—The throat of the animal was first shaved, after which an anæsthetic was given and the skin was sterilised with the cautery. The carotid artery was then exposed with sterile instruments, divided, and the blood collected in a sterile conical glass vessel.

In all cases the serum used for experiment was 24 hours old in contact with clot. Sterility controls for the serum were always put up and only those experiments are recorded in which the serum proved sterile.

2. *Estimation of bactericidal action.*—For this purpose the following methods were employed:—

(a) *Wright's capillary testing pipettes.*—The procedure adopted was that described by Professor A. E. Wright.⁴ Equal volumes of the test serum and an ascending series of dilutions of a 48 hours broth culture of bacillus pestis were brought together in the capillary stems of these pipettes. At the same time a parallel series of pipettes was prepared containing equal volumes of sterile broth and the ascending series of dilutions of the culture. All pipettes were then incubated at 37° C. for from 18 to 24 hours, after which the mixture of test serum or sterile broth and culture dilution was drawn up into the broth chamber. All pipettes were then incubated for three days at 37° C., after which the presence or absence of bactericidal action was determined by comparing the pipettes of both the broth and serum series. In cases of doubt as to the purity of the growth obtained the contents of the pipettes were blown out to agar and the resulting growth was subjected to the customary tests.

(b) *By the use of small test tubes.*—Equal quantities (50 cubic millimetres) of the test serum and an ascending series of dilutions of a 48 hours broth culture of bacillus pestis were brought together in small, specially constructed test tubes. These tubes were prepared from glass tubing, being blown and lipped in the ordinary way. The average length of the tubes was about 4.5 centimetres and the

capacity was about one cubic centimetre. At the same time a parallel series of tubes was prepared, each tube containing equal quantities (50 cubic millimetres) of sterile broth and the ascending series of dilutions of the broth culture. All tubes were then incubated at 37° C. for from 18 to 24 hours, after which 0.5 cubic centimetre of sterile broth was added to each tube, beginning in the case of each series at that tube which contained the highest dilution of the culture. All tubes were then incubated at 37° C. for three days, after which the presence or absence of bactericidal action was determined by comparing the tubes of the serum and broth series. In cases of doubt the purity of the resulting growth was ascertained by the usual methods. The strain of bacillus pestis employed was isolated from an acute case of bubonic plague. The dilutions of the culture were made in sterile watch glasses with sterile broth by means of Wright's diluting pipette. Enumeration of the culture was made from a 1,000,000 fold dilution, but owing to the nature of the growth of bacillus pestis in culture media the results were not very satisfactory. When the quantity of serum available was sufficiently great both methods of estimating bactericidal power were used simultaneously, but when, as in the case of man and monkey, only a small quantity of serum was available Wright's method alone was used.

Inspection of the accompanying table shows that in no case was any evidence of bactericidal power discovered. On the contrary, it was found that the serum of all the animals examined proved to be as good a medium for the growth of bacillus pestis as ordinary nutrient broth. Four observations were made with the serum of each animal but as the result in all cases was consistently negative, so far as bactericidal action was concerned, only one experiment is recorded for each animal. From these experiments it would seem that normal mammalian serum is devoid of any bactericidal action on bacillus pestis. The explanation of the immunity enjoyed under natural and artificial conditions of infection by some members of the order of mammalia must be sought in some other direction.

Bombay.

THE OLD AND THE NEW IN OCULAR THERAPEUTICS.¹

By A. MAITLAND RAMSAY, M.D. GLASG.,
F.F.P.S. GLASG.,

SURGEON TO THE GLASGOW OPHTHALMIC INSTITUTION; CONSULTING OPHTHALMIC SURGEON TO THE GLASGOW ROYAL INFIRMARY.

In the treatment of disease fashion undoubtedly influences the practitioner far more than he imagines. There is a tacit trust in authority, and certain things are done in certain circumstances without much consideration as to the why or the wherefore. While pathological research and physiological inquiry have accomplished much in placing the treatment of disease upon a more scientific basis and in making it more intelligent, more rational, and less and less of an experiment, yet the only true test of scientific generalisation is clinical experience. Practice is the touchstone of the validity of science, and while science has revolutionised many branches of medical work, and is certain to suggest still more and more new methods, it does not follow as a matter of absolute law that in every, or indeed in any, case the result will be what might have been anticipated from laboratory experiment. The ultimate aim of all practice is the cure or relief of the patient, and anything that will produce either result is worthy of attention and trial, even though it may not be in accordance with all that is yet known of scientific method. Therapeutics, therefore, though it aims at being a science, is still largely empirical, but being in reality an art it is none the less useful because it is empirical. Success in the art of healing is thus largely a matter of the physician's personal experience, and the great aim ought always to be to utilise experience to formulate a principle and so to permit the succeeding generation to appropriate the information laboriously accumulated by those who have gone before.

The great difficulty, however, is to analyse the experience

¹ A post-graduate lecture delivered at the Glasgow Ophthalmic Institution on Dec. 5th, 1905.

gained after a life long devotion to medical practice so that others may benefit from it. The old medical practitioner knows the right thing to do, and does it; but he often fails to communicate to another the exact reason of his action. His skill in the treatment of disease has about it just the touch of genius that distinguishes it from mere talent. It is personal and, unfortunately, for the most part dies with him. Others may copy his methods but the result obtained is usually very different, because, as the late Dr. John Brown says, "no man can explain directly to another man how he does any one particular thing, the doing of which he himself has accomplished not at once, or by imitation, or by teaching, but by repeated personal trials—by missing much before ultimately hitting." The young graduate, fresh from the university and full of the most recent theories as to the cause of disease and the action of remedies, smiles in a superior way as he speaks of the old-fashioned practitioner, whom, nevertheless, he is only too glad to see at his bedside when he himself is ill. Wherein, then, does the strength of the older man lie? It lies in this, that he treats his patient rather than the disease, recognising that he has a certain diathesis, a family history, hereditary proclivities, and the personal peculiarities which are termed idiosyncrasies. As it is popularly expressed, he knows his patient's constitution and he is also in most instances cognisant of his habits, consequently it is with recognised authority that at one time he whispers words of hope and encouragement and at another utters a timely and serious warning. The beginning and the end of his practice, therefore, is treatment, which is just what the medical student of to-day often tends to neglect; and by treatment I do not mean simply the administration of drugs but the making use of every agency or circumstance which can help to bring about the patient's recovery.

The weakness of the older men lay in their idea that disease was a morbid entity that had to be driven out of the system at all hazards and so their treatment was often inclined to be too heroic. They bled, they leeches, they blistered, they purged, they salivated all to extremes, and hence they brought upon themselves the ridicule of many a satirist. In his novel "Hard Cash" Charles Reade, for example, makes Dr. Sampson rail vigorously against anti-phlogistic methods and at an earlier period Molière wrote that "only strong and robust constitutions can bear their remedies in addition to the illness; the patient has only just enough strength for his sickness." While it is true that these methods were in many instances carried to excess and the ridicule richly deserved, we must remember that there is for all of them when properly employed a sphere of great usefulness. In no branch of medicine is this more obvious than in the treatment of ocular diseases, where in many cases leeching, blistering, and purging are employed with advantage and success. For example, in a case of severe irido-cyclitis if blood be taken freely from the temple by either the natural or the artificial leech, in most cases a change for the better at once takes place, pain is relieved, the pupil dilates, and congestion diminishes. Again, in a case of keratitis most gratifying results are often obtained by following the old-fashioned plan of blistering the eyelids with solid caustic; and in iritis, when the disease is tending to relapse time after time, the application of a blister often brings about such a change that recovery goes on afterwards without interruption. A more pronounced result still is obtained if the blistered surface be kept open by the application of an irritating ointment or by D'Albespeyre's paper and in all deep seated chronic inflammations an open blister largely contributes to the means of cure. When the inflammation is due to syphilis the presence of an open sore is, in my experience, most helpful, and therefore in such instances I have not the slightest hesitation in inserting a seton in the nape and keeping it there for several months. So strongly, indeed, am I convinced of the value of such measures that I feel that those who do not freely avail themselves of them deprive their patients of an important source of help. Then again, how great is the improvement that often comes to an injured or inflamed eye after free purgation by a large dose of calomel followed by a saline draught; and it has been demonstrated over and over again in iritis that the inflammation yields and the pupil dilates to atropine simultaneously with the slight soreness of the gums which indicates that the system is becoming affected by mercury. Oculists have never abandoned calomel and opium in the treatment of diseases of the

uveal tract, no matter whether they be of syphilitic origin or not.

In ophthalmology I think I may fairly say that the great contrast between the old and the new lies in the fact that, while the old masters made a great point of general treatment, the modern ophthalmic surgeon tends too much to look upon ocular therapeutics as mainly local and operative. The tendency is, in my opinion, a mistake, for I think it as important as ever always to lay down and to carry out a definite plan of general treatment which will deal not only with the eye but with the patient's whole condition. The want of familiarity with prescribing and the consequent tendency to take refuge in the use of proprietary drugs are often very unfortunate. A remedy which has been successful in one case may in another interfere with the digestion and assimilation of food and so do nothing but harm. Whenever a medical man finds any medicine, no matter how high its reputation, causing gastro-intestinal disturbance he should at once vary the preparation and the combination of drugs to suit the peculiarity of the patient, and he will be the most successful who can do this and at the same time not depart in the least from the line of treatment he has laid down for himself.

Great, however, as was the clinical skill of the old masters, and much as we may learn from them, there can be no doubt whatever that the advance of science and the increase of knowledge have thrown an entirely new light on the treatment of eye diseases. Let us look at some of the branches of the subject where this is specially true.

1. *Refraction*.—Up to the time of Donders there was no exact knowledge of the optical defects of the eye. All that could be said was that concave glasses improved myopia, convex ones presbyopia, and the selection of a lens for the one or for the other in any given case was simply a process of rough empiricism. It is true that the symptoms consequent upon errors of refraction were known to the old ophthalmologists, for in their writings they have, under the name of asthenopia, described this condition at great length, and in the realistic clinical pictures they have given there cannot be the slightest difficulty in recognising all the symptoms of eye-strain. They possessed, however, only a very hazy notion of the real cause of the difficulty. Mackenzie came very near the truth when he wrote that "one of the strongest proofs that the seat of the disease must be, in part at least, the apparatus of accommodation is the fact that the employment of glasses relieves the symptoms almost as completely as it does those of presbyopia," but in his classical treatise he has much to say upon other causes, which he divides into remote and proximate. Of the latter he writes that "as pathological anatomy has thrown no light on the seat or nature of asthenopia we are left altogether to conjecture respecting its proximate causes." He regarded the condition as "an infirmity much more to be dreaded than many disorders of the eye which, to superficial observation, present a far more formidable appearance." He looked upon the prognosis as "on the whole unfavourable" and gave it as his opinion that "in many cases it is our duty to declare the disease incurable, and to explain to the patient and his friends that all that can be done for it is, as much as possible, to spare the sight from exercise on near objects. If the patient is a young lad bound apprentice to a sedentary trade, and the disease, from its duration and its mode of origin, not likely to yield to treatment, we may advise him to turn shop-keeper, to apply himself to country work, or to go to sea; if a female occupied constantly in sewing, to engage in household affairs, or any other healthy active employment. Many a poor man have I told to give up his sedentary trade and drive a horse and cart; while to those in better circumstances, and not far advanced in life, I have recommended emigration, telling them that, though they never could employ their eyes advantageously where much reading or writing was required, they might see sufficiently to follow the pastoral pursuits of an Australian colonist."

These words were published in 1854, only ten years before Donders gave to the world his great work on the "Anomalies of the Refraction and Accommodation of the Eye," in which he demonstrated for the first time what is meant by ocular refraction and accommodation, what changes they undergo with age, how they are related to the movements of the eye, and how they may be neutralised or corrected. Had it not been for Donders the brilliant discoveries of Helmholtz, which went far to solve the much-disputed question of the accommodation of the eye to different distances, might not even yet have been utilised

for the good of mankind, notwithstanding that they are in our daily life of the utmost importance for persons of every age and of every class and have value that will persist for all time. Few discoveries, indeed, have been more beneficial in their results, for no one can estimate the number of those who in former days would have been compelled through visual disability to abandon their "position, their prospects, and their duties in life," but who through the prescription of suitable spectacles have been restored to health, to happiness, and to usefulness.

In dealing, however, with those who complain of symptoms of eye-strain, it ought always to be remembered that the prescription of glasses, although essential and all important, must not be regarded as the whole treatment. It is not enough in the case of the young simply to adjust lenses suitable for the correction of the error of refraction. A quick estimate must also be formed of the patient's general strength, for it must not be forgotten that, although the demand for work made upon the ciliary and the extra-ocular muscles may not be unreasonably great in itself, yet it may be altogether excessive in relation to the individual in whom it is made. While, therefore, the error of refraction ought always to be carefully corrected so that the eye may be used under the most favourable conditions, every effort must also be made to develop and to strengthen the whole muscular system.

The amount of attention which has, through the examination of the eyesight of school children and otherwise, been of late directed to this subject has unfortunately given rise to a serious evil. The number of people who now find that they require spectacles has called into existence a class of opticians who style themselves "Refractionists" or "Optologists," and who try to promulgate the idea that as "spectacles concern the optical part of the eye only" they are perfectly competent to prescribe as well as to sell glasses. A too credulous public have readily availed themselves of the services of these men under the impression that they are obtaining all the benefit that could be got from a specialist without having to pay his fee. The eye is the most delicate organ in the body and its diseases are at times so subtle that their existence and nature require the most skilled examination and attention, consequently it is not difficult to imagine the amount of harm that may follow the counter prescribing of the ophthalmic optician. I am perfectly well aware that some medical men are in the habit of referring their patients to such advisers, but why they should delegate an important part of their duty to an unqualified person it is very difficult to understand. The eye is not only in the body but it is also of the body, and the treatment of its optical defects requires the physician's skill just as much as does the treatment of its diseases. Opticians would confer a far greater benefit on the public if they would utilise their increased knowledge to perfect the mechanical parts of spectacles and eye-glasses, and leave the prescribing to those who are, by their medical knowledge and special training, fitted to do the work efficiently.

2. Mydriatics.—These, owing to the use of the ophthalmoscope and the study of refraction by the shadow test, are nowadays much more generally employed than was once the case. One of the commonest of them is atropine, which has for long occupied such a high place in ocular therapeutics that the uninstructed have come to look upon it as a panacea for all the ills that the eye is heir to, and consequently the abuse of the drug has done much harm. In simple conditions, where its administration was unnecessary, much inconvenience has been caused by paralysis of the accommodation, while in the elderly its use has at times precipitated an attack of acute glaucoma. It ought to be a golden rule, never to be forgotten by anyone who treats diseases of the eye, that atropine should in no case be instilled in a patient over 40 years of age until the intra-ocular tension has been carefully tested and found to be normal. The caution that atropine ought never to be used in glaucoma cannot be repeated too often. For examination purposes its disadvantages are obvious. It not only dilates the pupil but it paralyses the accommodation, and its effects remain for several days greatly to the inconvenience of the patient. Indeed, should he be suffering from an affection of the retina or choroid and there be any increase of the disease during the time the eyes are under the influence of the drug, he may easily be tempted to blame the atropine used to facilitate an ophthalmoscopic examination for making his sight worse. A demand has therefore arisen for a mydriatic which will act quickly and the effects

of which will pass off quickly, and which, while it will dilate the pupil to the maximum, will interfere as little as possible with accommodation. The manufacturing chemist has supplied several, of which the most important is the very expensive homatropine. This is both a mydriatic and a cycloplegic, but its effects pass off in a few hours. It is employed in a 1 per cent. solution and is, in combination with cocaine, much used in the estimation of refraction by the shadow test. Other two excellent preparations are mydrine and euphthalmine, which dilate the pupil quickly and interfere but little with accommodation. They are of great value for improving sight in nuclear cataract or in central opacity of the cornea, as well as when one is making an ophthalmoscopic examination.

3. Antiseptics.—Long before anything was known of bacteriology the three favourite drugs employed in the treatment of inflammation of the conjunctiva were nitrate of silver, sulphate of zinc, and perchloride of mercury. All three have powerful antiseptic action and that property explains the favour in which they were held by the older ophthalmic surgeons, who, however, reached their conclusions wholly as a result of extensive clinical observation. It was known that nitrate of silver was of special value in purulent ophthalmia, that sulphate of zinc was almost a specific in certain forms of catarrhal conjunctivitis, and that perchloride of mercury was generally useful in inflammation both of the lids and of the conjunctiva. A study of bacteriology affords a ready explanation, for it has been proved that salts of silver are fatal to gonococci, that sulphate of zinc is fatal to the bacillus of Weeks, and that perchloride of mercury is inimical to all forms of microbial life. This is a good example of how a method of treatment arrived at in the first instance by clinical experiment has been amply justified and confirmed by the increase of knowledge. The old ophthalmic surgeons are entitled to the credit of having been the pioneers in the use of antiseptics, though they could not explain how or why the beneficial results came about, while the general surgeon did not fully avail himself of these germicides till their action was explained by the study of bacteriology.

Ophthalmology received advantage in turn from the investigation and discussion of the germ theory. The researches of Pasteur and their practical application by Lister and his followers made successful operative interference possible in many cases from which the surgeon had hitherto been debarred, and so gave a great stimulus to surgery of every kind. In the case of that of the eye, however, there was a difficulty in carrying out full antiseptic methods; owing to the extreme delicacy of the structures it is not possible to employ antiseptic solutions strong enough to kill the micro-organisms without at the same time injuring the conjunctiva. In ocular surgery, therefore, the field of operation is prepared by freely flushing the conjunctival sac with bland solutions. By that means the germs are mechanically washed away and their numbers are consequently so reduced that they are unable to exercise any injurious influence over the healing of a wound. If infection has taken place, however, an antiseptic is necessary, and of all those employed in ocular surgery none is so generally useful as silver. In the old form of the nitrate it has no doubt many disadvantages. Its caustic action gives rise to a superficial eschar and thus it cannot penetrate deeply into the tissues. Its use is accompanied by great pain and after a time it produces dark staining of the conjunctiva—argyrosis. In spite of these drawbacks, however, the nitrate can still in many cases be employed with advantage, although it is now being in great measure supplanted by other salts of the same metal which, while they are strongly bactericidal, possess fewer undesirable qualities. Out of the large number of these which the manufacturing chemist has placed on the market I shall select the three with the clinical value of which I am most familiar—protargol, collargol, and argyrol. Although the first contains only 8.3 per cent. of metallic silver, as contrasted with 30 per cent. in each of the others, it is by far the most irritating as well as the one most liable to cause argyrosis. Each, however, has come to occupy a distinct place in my practice. In chronic inflammation of the conjunctiva and the edges of the eyelids protargol, in from 10 to 25 per cent. solution or ointment, brushed vigorously over the affected parts, produces far quicker and better results than are to be obtained by any other method of treatment with which I am acquainted. In recent wounds of the eyeball I prefer collargol and employ it for the most part in

the form of gelatine waters containing 10 per cent. of the drug, but I also use it in solution and as ointment in strength varying from 5 to 20 per cent. If the injured surface be aseptic the collargol gelatin at once adheres to it, thereby sealing the wound and covering it up completely with an antiseptic plaster under which healing goes on with great rapidity. If, however, there be any sepsis the silver salt will not adhere to the wound, and consequently the presence or absence of the staining forms a trustworthy guide in prognosis. Collargol is almost always successful in its action and it has also a wonderful power in clearing up recent opacities of the cornea, whether these be due to injury or to disease, but on very rare occasions it induces so much chemosis and causes such severe pain that its use requires to be discontinued. In acute conjunctivitis argyrol gives the best results. Of the three it is the least irritating and it possesses quite a wonderful power in lessening discharge and in relieving pain. It can be used in as great a strength as 50 per cent. and, like the other preparations I am speaking of, it may be applied either in solution or as an ointment. Although it is said to penetrate deeply into the tissues, on only two occasions have I seen marked discolouration of the conjunctiva follow its use. It is so non-irritating that it can safely be injected into the anterior chamber to control intraocular suppuration and in this connexion I have obtained better results from it and from collargol gelatin than from the iodoform rods so highly recommended by Haab. In the treatment of purulent ophthalmia, either in the adult or in the new-born child, it is, in my opinion, the most valuable remedy that we possess; but the best results are obtained by brushing the whole palpebral conjunctiva once thoroughly with a 2 per cent. solution of nitrate of silver at the outset of the disease and afterwards applying a 20 per cent. solution of argyrol every few hours, the frequency of these applications being regulated solely by the amount of the discharge. In blennorrhœa of the lacrymal passages, after the nasal duct is clear of obstruction, the injection of solution of argyrol into the tear-sac checks suppuration and thereby hastens the cure of what in former days was one of the most tedious of diseases.

The great aim of modern surgery being to prevent, or to control, sepsis, a very large number of drugs for this purpose have in recent years been put on the market by manufacturing chemists, accompanied by numerous testimonials in praise of their highly antiseptic properties. I need only remark concerning most of these that the results obtained in a test-tube experiment are not always confirmed in actual practice. Two, however, can be confidently recommended—chinosol and trikresol. The former in the strength of 1 in 400 is of undoubted value in the treatment of infected ulcers of the cornea, and the latter, 1 in 1000, forms an admirable lotion for removing discharge from an inflamed conjunctiva.

There is one form of ulceration of the cornea—serpiginous ulcer—which, when it does show itself, follows as a rule some trivial injury, but the truly infective nature of which is made manifest by its exceeding painfulness and by the rapid appearance of pus in the anterior chamber. It takes its name from the stealthy and yet steady way in which, if uncontrolled by treatment, it creeps over the whole surface of the cornea and destroys it completely. I well remember with what grave apprehension this disease used to be regarded, and how the surgeon, having exhausted all the known resources of therapeutics, had to stand by and watch the cornea melt away. Nowadays all that is changed, for by the thorough and timely application of the actual cautery the process of ulceration can be arrested, and, if care be taken to prevent reinfection, and if the tendency to the formation of anterior staphyloma be obviated by keeping the patient in bed till cicatrization is complete, useful vision can in many instances be restored. Indeed, in the treatment of serpiginous ulcer, once so formidable and so intractable, modern ophthalmology has achieved one of its greatest triumphs.

For the purpose of controlling and arresting infection some have in recent years advocated the injection of weak solutions of mercurial salts beneath the conjunctiva, on the ground that the nearer to the site of the disease the remedy is applied the more likely it is to prove effective. My own experience of this method in the treatment of suppurative keratitis or of infective irido-cyclitis does not warrant me in speaking strongly in its favour; but in some diseases—in choroiditis, for example, accompanying high myopia, and in

detachment of the retina—where the usual remedies have but little effect, I have obtained very encouraging results from the use of subconjunctival injections. The fluid which I usually employ is 8 per cent. chloride of sodium in a 1 in 2000 solution of bichloride of mercury, 5 to 20 minims being injected slowly beneath the conjunctiva, which as the fluid enters rises in a bleb. The great drawback to this method of treatment is its exceeding painfulness, but the suffering can be largely mitigated by using only chemically pure chloride of sodium and by adding to each dose immediately before injection a few drops of a 1 per cent. solution of cocaine.

4. *Anæsthetics*.—These are "remedies by means of which the sensations of pain are dulled or abolished." They are divided into two classes—local and general.

(a) *Local anæsthetics*.—Of these, cocaine is in my opinion *facile princeps*. It was introduced by Koller in 1884 and its use has been an inestimable boon to ocular surgery. If any one has had a foreign body removed from his cornea without cocaine and has had, also, at a later period, the same operation performed with the eye anæsthetised by means of that drug, he will realise to the full the difference in this respect between the old and the new. The use of cocaine has, however, certain drawbacks. It dilates the pupil, disorders the accommodation, and acts injuriously upon the corneal epithelium, producing in some cases actual inflammation. Now, in my opinion, these disadvantages may for the most part be avoided if the solution employed be weak. I never for any purpose use a greater strength than 2 per cent., and I always make the patient keep the eye closed after the drops have been instilled. If the operation be prolonged I take the additional precaution of instilling a few drops of 5 per cent. chloroform oil into the conjunctival sac immediately before applying the bandage. In the case of a tarsal cyst, or in cauterising an ulcer of the cornea, however, I apply a small quantity of solid cocaine directly to the part about to be operated upon. When the drug is used in that way it seems never to be followed by any evil effect. If it be necessary to reach the deeper parts of the eye, for example the iris, a few drops of the 2 per cent. solution may be injected beneath the conjunctiva.

The drawbacks that I have mentioned have, however, led some to discard cocaine for holocaine, which in a 1 per cent. solution is a very trustworthy anæsthetic, though as it possesses highly toxic properties it cannot without danger be injected beneath the skin or conjunctiva or along the tear passages. In my experience holocaine acts more slowly than cocaine but penetrates more deeply, and I find it a most valuable addition to that drug in all operations in which it is necessary to cut the iris. My favourite combination for this purpose is cocaine hydrochloride 2 per cent. and holocaine hydrochloride 1 per cent. dissolved in solution of adrenalin chloride, 1 in 1000, freshly prepared immediately before being used. The employment of this mixture enables an operation for cataract to be performed without the slightest pain. Sometimes an oily solution is preferable to an aqueous one but in that case the pure alkaloid must be used and not a salt.

I have just mentioned adrenalin, which is one of the most important of the additions that have been made in recent years to the resources of ophthalmic therapeutics. Its marvellous power of contracting blood-vessels enables the surgeon to carry out most operations on the eyeball almost bloodlessly, while the exsanguine condition of the conjunctiva which it produces facilitates the absorption of such drugs as cocaine, atropine, and eserine, and so renders their action more powerful. Stovaine, eucaine lactate, alpin, and cocaine, of which the last has already been mentioned in connexion with the use of subconjunctival injections, are all trustworthy local anæsthetics and are much less toxic than cocaine but I do not think their virtues so outstanding as to make me prefer them in ordinary work to that drug used in the way I have described. Occasionally they may prove of considerable service, but up till now I have seen no reason to discard an old friend for the sake of the new preparations continually being introduced by chemists.

(b) *General anæsthetics*.—In ophthalmic surgery the use of local anæsthetics has to a large extent removed the need for general anæsthesia, but when one is dealing with a young child or with a nervous, refractory adult, or operating on an inflamed eye or enucleating the globe, a general anæsthetic is still necessary. In these circumstances I prefer chloroform but the patients must be brought thoroughly under its influence, for if they are only partially anæsthetised there is

a risk of vomiting or of awkward movements of the eye at a critical point of the operation, and in enucleation of the eyeball there is also the risk of dangerous collapse at the moment the optic and ciliary nerves are divided. For short operations where a general anæsthetic is deemed advisable I prefer to employ chloride of ethyl preceded by nitrous oxide gas. The use of this combination produces a profound quiet anæsthesia lasting from one to two minutes. The chloride of ethyl is, however, most suitable for women and children, for occasionally it causes men to become greatly excited before they pass thoroughly under its influence.

5. *Analgesics*.—These are "remedies which relieve pain," and they are, like anæsthetics, local and general. Of the former I shall mention only dionine. It is a derivative of morphine, and in 5 per cent. solution is one of the most valuable agents which we possess for the relief of deep-seated pain—e.g., in glaucoma, iritis, scleritis, &c. When dropped into the eye it causes at first a smarting and burning sensation accompanied by chemosis of the conjunctiva and swelling of the lids. These symptoms are sometimes very pronounced and may alarm the patient greatly if he has not been forewarned of the probability of their occurrence and told that they speedily pass off. This lymphagogue property of dionine is intimately associated with its power as an analgesic, because only after a good reaction is there much relief of the pain. This property also explains its power in promoting absorption of inflammatory deposits in the cornea. Its action in this way, very satisfactory in itself, is greatly increased if it be used along with collargol. In my experience the best results are obtained when a 5 per cent. solution of dionine is instilled in the morning and a disc of 10 per cent. collargol gelatin is placed in the conjunctival sac in the evening. I am satisfied that this method of treatment hastens the clearing of the cornea after an attack of ulceration or of interstitial keratitis.

Of general analgesics morphine injected subcutaneously is the most satisfactory but the physician ought to administer the dose himself and not intrust the use of the hypodermic syringe to a nurse. Unless the circumstances are very exceptional the best results are got from small doses—from one-eighth to one-sixth of a grain—repeated if necessary, and if the amount given be thus restricted it is seldom that there is any subsequent sickness and digestive disturbance. If I think there is likely to be much suffering after an operation I give a small hypodermic injection of morphine before the patient is removed from the table. This insures several hours of continuous repose and so not only prevents the harm that arises from restlessness but also gives nature a healing chance of which she is never slow to avail herself to the utmost. Of the many newer pain-killing drugs supplied by manufacturing chemists one of the best in ophthalmic practice is aspirin. Given in 15-grain doses in iridocyclitis and other deep-seated inflammations of the eye, whether they be of rheumatic origin or not, it acts like a charm. Should it tend to cause depression it is wise to combine it with caffeine, and when the patient is sleepless its efficacy is greatly enhanced by the addition of ten grains of trional.

6. *Serum-therapy*.—No lecture, however fragmentary, can be considered as dealing with the new if it does not make mention of serum therapeutics. This, indeed, though it is typical of the trend of recent investigation, is in reality as old as nature herself, for we now know that it is her own method of curing disease. The normal blood serum contains protective substances which prevent noxious micro-organisms from doing harm, and infection can take place only when bacteria are present in greater numbers than the natural antitoxins can overcome. The study of the subject is as yet in its infancy, but the researches of Wright and others have demonstrated "that there exists in the normal serum, and there exists in larger quantity in the serum of the successfully inoculated patient, an element which enters into chemical combination with the micro-organism in such a manner as to prepare it for phagocytosis." As this substance can be measured, the use of artificial serums is placed upon a truly scientific basis and we can now employ them in perfectly determinate doses with exactitude and confidence. Hitherto the drawback in prescribing these powerful remedies was the risk of doing harm, but there is no reason to doubt that with the advance of science and the increase of knowledge serum treatment will come to bulk more and more largely in medical practice. Here we have the exact knowledge of the new dealing with a problem that the old tried to solve in a blindly empirical way. The

humoralists argued that every morbid process arose from a disordered state of the blood and so they strove to restore this to a healthy condition. In modern times the discovery of micro-organisms led to the idea that they were the sole factors in causing disease and the tendency was to attempt to destroy the bacteria by antiseptics. Both efforts resulted in failure, for in the first case all attention was given to the soil and in the second to the germ. Now, however, that the relations of these have been brought into proper perspective, we know that the microbes can be fought successfully only by immunising the blood. When we remember how many eye conditions are simply the outcome of morbid constitutional states we can readily see how useful serum treatment may become in ocular therapeutics.

I know that in this lecture I have merely touched the fringe of a wide subject, but this is only a *résumé* of my own practice at the present moment and not a review of recent advances in ocular therapeutics. Those who wish for fuller information I must refer to Darier's papers and to the admirable lectures by Sydney Stephenson in the numbers of the *Medical Press and Circular* for August, 1905; of the great advances which have been made in electro therapeutics in the application of the x rays and other forms of radio-activity in the treatment of ocular affections, there is now no time to speak. The possibilities that underlie the action of the far-reaching ray world outside the narrow limits of the visible spectrum are so great as to transcend the bounds of even the most powerful imagination; but, without doubt, these therapeutic measures are full of promise and when we think of them we are filled with expectancy and hope. As yet, however, the results obtained are not such as to justify dogmatic statements, and at present it can only bring discredit on ourselves and on our methods to make such an assertion as that under the influence of ultra-violet or any other rays "cancers are cured." Nature, nevertheless, knows no pause and there can be no finality in knowledge. The old and the new must always be in contact and yet always in contrast. Progress implies a steady advance, and so on our onward course we must leave much behind. The great point is that from what we abandon we should always pick out and take with us whatever is good and true. Only then can we form a sure foundation on which to rear the superstructure of the new, and as we rear we must make certain not only that our foundations are firm but that each course in our building is secure. Nothing can be taken on trust. Not till a thing has stood the test of experience can we be certain that we have in it obtained what is reliable. To go sure we must go slow and never be led astray by the will-of-the-wisp glamour of novelty for novelty's sake. This will lead inevitably to mere floundering in the bog of charlatanism. Let us, therefore, prove all things and hold fast to that which is good, whether it be in the old or in the new.

Glasgow.

MEDICAL ATTENDANCE ON THE WORKING CLASSES.¹

BY J. H. KEAY, M.A., M.D. EDIN.

THIS is an age of social problems. They are being constantly discussed not only in the press but by the man in the street. Everyone seems to be trying to solve such vexed questions as tariff reform, the unemployed, and the depopulation of the rural districts. Of scarcely less importance is the problem we have met here to discuss to-night—viz, Medical Attendance on the Working Classes. It is a trite saying but a true one that the working man is the backbone of the country and as it depends on the physique and *morale* of the working classes whether the country stands or falls no consideration that affects their standard of health and wage-earning capacity can be otherwise regarded than as of the utmost importance. It is quite true, however, that this problem does not bulk so largely in men's minds as those we have just mentioned. There are many medical men who have not regarded it seriously and the consequence has been that the problem of medical attendance on the working classes has been left very much

¹ A paper read before the West Kent Medico-Chirurgical Society on April 6th, 1906.

in the hands of the laity, while the attempts of the laity to solve it have generally ended in some form of unreasoning and misguided charity that has done as much to demoralise as to help the suffering poor.

Notwithstanding the increased standard of comfort in these days there is no denying it that in sickness the position of the more poorly paid of the working classes in this country is often painful in the extreme. We find from the Registrar-General's reports that in some parts of Scotland not more than half of those who die have been attended by a medical man. When in practice some years ago in Scotland my nearest medical neighbour to the north was distant 38 miles. In the intervening district were shepherd's and farm labourers who were often poorly paid and when a long medical attendance was required the income of three or six months in the year would barely suffice to pay the ordinary fees of a medical man. As in these outlying districts the working classes though poor are generally honest and detest applying to the parish or being beholden to charity, it was sometimes my painful experience when six or eight miles on my way to see a patient to be met by a messenger who would tell me I need not go farther, that they had put off as long as they could, and that the patient was dead. I need not speak of the poorer districts of Ireland where a recent Commission has shown that medical men who have toiled hard for a livelihood have often ended their days in the utmost poverty. What advantage the sick are to derive from medical men who are themselves broken down through old age or overwork and suffering from chronic financial worry I know not.

It is not, however, to the provinces or outlying districts I ask your attention to-night but to the million and a half or more in London who are not earning a living wage and who certainly are not in a position to pay a doctor's bill. Now in trying to solve this problem there are two principles I would lay down which I trust will not meet with much opposition: (1) that if any conclusion is to be arrived at as to the best means of attending the labouring class it must be by those best acquainted with the subject—namely, by medical men themselves; and (2) that if we wish the public to be guided by any conclusion we arrive at we must first convince them that we have not considered the question from a merely narrow-minded or selfish point of view. It seems quite time that we had made up our minds whether we desire the public to regard us as a trade or a profession. If, on the one hand, our main end in life is to extract money from our patients and the public then assuredly we are a trade. If, on the other hand, we are prepared at some sacrifice to follow the traditions of the past and to regard our patients' welfare and the public health as the first consideration we may claim to be a profession. It has hitherto been generally admitted that there is no body of men more broad-minded and self-denying than medical men, but I cannot help thinking that if the public were to read the letters and articles that have recently appeared in our journals they would be forced to the painful conclusion that there are some medical men at least who are but little concerned as to the wants of the suffering poor but who are keenly alive to their own individual and selfish interests.

But to proceed. In discussing the question of medical attendance on the working classes I do not intend to refer to foremen, skilled artisans, and others earning £2 or more a week. These men can quite afford to pay a doctor's bill. Take even the case of the man earning, say, 30s. to 35s. a week. He may find it a difficult matter to pay a doctor's bill but it would probably be to his advantage if he contrived to do so. It is the position of the million or more in London who, according to Booth and others, are living in households where the earnings are not more than 25s. a week that I wish you specially to consider. These men are not earning a living wage and after paying high rents they are certainly not in a position to pay a medical man half-a-crown or even one-and-sixpence a visit when there is a prolonged attendance. How, then, are they to be medically attended? The reply is at once forthcoming—that in our poorer districts there are any number of medical men willing to attend them for less and whose fee for advice and medicine is sixpence or even fourpence. But can this attendance be regarded as satisfactory? Far be it from me, in the present disorganised state of the profession, to blame the sixpenny doctor. I detest the cheap sneers of prosperous medical and business men at those who are compelled by the force of circumstances to do cheap practice. Can a medical man living in a poor neighbourhood do

otherwise when he has to compete with hospitals giving medicine and advice free of charge, or, worse still, for the few coppers that sooner or later come to be regarded by the labouring classes as the correct value of the attendance? Among those doing cheap practice one finds here and there a medical man who is not doing so by compulsion but because he believes it better to accept small sums than that the poor should be utterly demoralised by charity. To this there is the obvious objection that a medical man charging small fees cannot always carefully inquire into a patient's circumstances and so has always on his list a number who are quite able to pay an adequate fee. It must be admitted, however, that the greater number who adopt cheap practice do so because they regard it as remunerative, and doubtless it can be made remunerative if no time be given for diagnosis and the patient receives for any symptom or disease of which he chooses to complain medicine doled out from cheap stock mixtures in such doses that he must return day after day for a fresh supply. This treatment may please the ignorant patient but it is a great loss to the wage-earning power of the community. It has now, I fear, however, become so prevalent that cheap practice cannot be regarded as an ideal solution of the vexed question of medical attendance.

But why, say some medical men with whom I have spoken, trouble about these people? Let them apply to the parish. The medical men who speak thus are not, I may say, those who practise in the poorest districts and depend to a large extent on the small but welcome fees of the working classes, nor are they the men who are best acquainted with the subject. It is quite true that a person not receiving parish relief may readily get an order for medical attendance from the parish, and that often with little or no difficulty, as a relieving officer well knows that the consequence of his refusal may be a censure from the coroner or a Local Government Board inquiry. By this means the burden of medical attendance on the poorer labouring classes is thrown on the rates. To this many would probably offer no objection provided they were assured that medical orders would be given to those only who are really deserving. To medical orders there is, however, the strong objection that they are a prolific source of pauperism. The medical order is often asked for, not on account of illness, but because by this means an order may possibly be obtained for food or stimulants, and when this order is once got no long time generally elapses before the family are in receipt of relief in the regular form. In connexion with this matter one cannot fail to note the new departure at Lambeth. The Lambeth guardians, with the consent of the Local Government Board, have appointed as parish doctors men who give their whole time to attending paupers and those who obtain medical orders. What the result of this new departure may be it is as yet too soon to say, but no one can fail to perceive that it may have far-reaching consequences and entirely alter our mode of practice by placing on the rates the burden of medical attendance not only of paupers but of the more poorly paid of the working classes.

A wider scope is also being given in some districts to Poor-law infirmaries where not only the destitute are admitted but workmen suffering from accident and others who recognised that as good medical attendance and as much comfort are to be obtained in some of our infirmaries as in the regular hospitals. In the borough of Lewisham, for example, there happens at the present time to be at the head of the infirmary an extremely popular and able medical officer and the consequence is that many enter the infirmary who would otherwise go to a regular hospital. There is much to be said in favour of this system and as rates are largely paid by the working classes the logical issue is that a working man who enters an infirmary does more to preserve his independence than when he enters a hospital. At the same time, it must be said that it is extremely doubtful whether it is well that respectable working men should enter infirmaries with their traditional associations and occupy the same wards as the actually destitute, or whether the time has yet arrived when medical attendance on artisans and small shopkeepers should be thrown on the rates.

As medical men we must then admit that the problem of attendance on the labouring classes has not yet been solved either by the Poor-law or the cheap medical man. Do we then agree with that large section of the charitable public who evidently believe that it can be solved by hospitals? Burdett tells us that considerably over 2,000,000, or about half the population of London, are attended by hospitals or Poor-law institutions. Have we not then in hospitals ample

provision for the wants of the labouring poor? Unfortunately not. Medical men well know and the charitable public are beginning to recognise the fact that the 2,000,000 who frequent the hospitals are not all poor, that many of them are well-to-do, and some of them in affluent circumstances, and that the overcrowding of hospitals by this class is putting the poor in the background and preventing them from receiving the attention they ought from the over-worked medical staff. Hospital physicians and surgeons may be wroth with me but I cannot help expressing my honest conviction that those suffering from trivial and sometimes even from serious illnesses are as well attended by the sixpenny doctor as in the out-patient departments of some of our hospitals and, according to the figures of the Hospital Sunday Fund, at one-third or one-fourth the cost.

I would not have thought it necessary to say another word as to the overcrowding and abuse of hospitals were it not that their abuse has been practically denied in a special report published a few weeks ago by the Metropolitan Hospital Sunday Fund. The report begins with the following pious resolution which was unanimously adopted: "The committee is of opinion that the serious increase in the number of out-patients is detrimental to the welfare of the hospitals and patients inasmuch as they are a burden on the funds of the hospital and prevent the hospital staff from giving the necessary attention to serious cases." Unfortunately, however, the committee of the Metropolitan Hospital Sunday Fund do not appear to be a logical body, for in the same report they proceed to formulate the following conclusions: 1. "That notwithstanding the large number of attendances in the out-patient departments of the general hospitals the hospitals have hitherto increased their accommodation and qualified staffs to an extent sufficient to enable them to cope with all such cases." 2. "That there is not any serious abuse of the out-patient departments and that any which may exist can be met by a competent staff visiting the homes of the patients." As to the remedy proposed which would certainly require an enormous number of relieving officers we might point out that patients do not always visit the hospitals nearest them. How, then, can their homes be visited? This is a minor matter. But can any sane man affirm that half the population of London is so poor that they cannot pay a fee to a medical man? Is there a general practitioner in London who cannot point to endless instances of families with good and even large incomes who from the beginning of the year to the end of it are visiting hospitals and receiving gratuitous medicine and advice? And what is the moral effect of this system? A large number of the middle and even the upper classes by lying and fraud succeed in imposing on hospitals. When they have had free advice from the hospital physician they see no reason why they should pay their family doctor and it is but a further step to discover some means of circumventing their baker and grocer. There can be no doubt that hospitals confer an untold blessing on many but it is also painfully evident that without different safeguards from those we have at present they act as a not unimportant factor in demoralising a large section of the community.

Notwithstanding the many abuses connected with hospitals it must be admitted that ever since the abolition of monasteries they have not only been a necessity but done excellent work. A few, but only a few, think otherwise. When a few years ago I was one of a number who were trying to establish a small hospital in a provincial town we were met with the following objections from the wealthy employers. They held that their town which had no hospital was in a better condition physically and morally than other towns that had hospitals; that their working classes had always been self-respecting and that their moral tone would be lowered when they became the recipients of charity; and that hospitals have always attracted a crowd of loafers and impoverished districts in which they are placed. They further pointed to the condition of many out-patient rooms and regarded it as one of the darkest blots on our civilisation that a crowd of people suffering from all kinds of disease, infectious and otherwise, should be huddled together for hours in an atmosphere laden with noxious germs and filth. Arguments of this sort would not appeal to those living in London and the south, who are accustomed to point to hospitals as the crowning triumph of our modern civilisation.

If the abuses connected with hospitals are to be remedied we must clearly perceive from whom they proceed. 1. First of all we have the general public, many of whom are engaged in contriving how they can get something for nothing, and

if the committee of the Hospital Sunday Fund is not quite logical we can scarcely blame their subscribers for concluding that because they contribute a few coppers to a hospital they are entitled to receive medicine and advice free and without question. 2. Hospital managers are also to blame in trying to swell their numbers by advertising in a manner that would disqualify a private practitioner, knowing as they do that it is by pointing to large numbers they can most effectually appeal to the charitable public. The detestable system of letters, though much inveighed against, has not yet received its death blow, and yet will anyone say that it is reasonable that hospitals rather than lose a subscription should admit with little and often no inquiry those well able to pay for medical attendance? A little more courage on the part of hospital committees would soon banish many abuses. Take only one example. Many single men are now treated in hospitals for accidents which do not afterwards incapacitate them from work but for which they receive compensation. When they leave the hospital after several weeks' or months' free board and lodging they find themselves entitled to a considerable sum. In cases I myself know this money has been so utterly wasted in idleness and debauchery that the men have become a curse to their neighbourhood, and yet I have not heard of a single instance where before leaving the hospital they have even been asked for a subscription. 3. But it must be admitted that the blame does not rest entirely with the public or hospital committees. Are medical men themselves entirely free from blame? One cannot help thinking that the great majority of hospital physicians and surgeons are enthralled by their environment. How few of them seem to have any qualm of conscience or the courage to make a protest even though, if they but think of it, they must clearly recognise that in attending so large a number without fee they are committing a grave injustice against many a struggling fellow practitioner. But it is not only the medical staff of hospitals that is to blame. It is well known that the overcrowding of the out-patient departments is often in no small measure due to men doing contract practice, many of whom are but too ready to avail themselves of this means of getting rid of a troublesome or anxious case. To so great an extent has this gone in the past that surgery has now practically passed out of the hands of the general practitioner. I can vouch for it that more than 95 per cent. of accidents in this district are treated in hospitals or Poor-law infirmaries. Employers say that it is useless to send them to medical men, that medical men are not always at home, and they find that even when they are at home, after rendering first aid, they almost invariably send the patient to the hospital. Time was when the employer paid the medical men in his district for attending to accidents. The employer now sends his subscription to the hospital, and it must in common fairness be admitted that the general practitioner has little or no right to complain.

It is thus evident that the interests of so many are involved in the overcrowding and abuse of hospitals that it will now be by no means easy to get rid of them without revolutionising the whole system. Some already go so far as to say that the abuse is so chronic that the only remedy is municipalisation. The conclusion is natural in the present position. There seems to be a tendency for the rich to lessen their subscriptions and for hospitals to rely more on payments made by working men themselves. If a great number subscribe, but not all, why then, it is said, not compel all to subscribe in the form of rates? Not a few of the members of the London County Council are, I understand, strongly in favour of this issue. I cannot trespass on your patience by discussing its merits and demerits, but this much I must say: that if medical men on the staff of hospitals are paid by the State and those in general practice are not the result must sooner or later necessarily be the almost complete exit of the family practitioner and a further severance of those family ties on the maintenance of which the material prosperity and character of a nation so largely depend.

Is it, then, too late in the day for us as medical men to find a remedy? I believe the remedy is in our power and it only needs a little self-abandonment and enthusiasm on our part to obtain it. Our thanks are due to those members of the British Medical Association who have toiled hard in this matter and to the proposals put forward by them I can see no reasonable objection. The system is already in full working order at the Bolingbroke Hospital, which provides not only for Wandsworth and Clapham but for the poor of

Battersea, and I understand that the President of the Local Government Board is justly proud of the share he took in bringing it about. The *modus operandi* has been well described by Dr. G. S. Hughes, the medical superintendent, who gave me these cards which explain his words which I now quote: "In the casualty department all cases are seen once and attended to by the casualty officer. If further treatment is required the patient is given a card which has to be brought signed by a medical practitioner. In the out-patient department the surgeons and physicians do not see patients unless they are accompanied by their own medical attendant or bring a card or letter from such medical attendant. No medicinal treatment is given either in the casualty or the special out-patient departments. If medicine is required it is given by the patient's own medical man." It is easy to perceive how great a gain this must be in the long run to the consultant, the practitioner, and the public in general. If this be the remedy, and I certainly think it the best, then by all means let us work for it and see to it that institutions so noble and beneficent in character be freed from abuse and conserve the purpose for which they were designed.

But this brings us to the consideration of contract practice, as without contract practice radical reform in hospital management seems impossible. If the report on this subject made by the medico-political committee of the British Medical Association and published in July last has not been read by every medical man I certainly think it ought to be. There have been some cheap sneers at this report. I certainly regard it as most valuable and the members of that committee as deserving the best thanks of the profession for their painstaking, elaborate, and unbiased statement. There are some salient points brought out by this report: (1) that contract practice is often badly paid; (2) that there are many paying small contract sums that could well afford to pay a doctor's bill; (3) that the contract patient often expects more attendance than is reasonable, an amount of attendance, in fact, that would be resented by a private patient; and (4) that there is a possible tendency for men largely engaged in contract practice to become slipshod and superficial in their work. While we readily admit that there is much force in all these objections, there are, I should think, but few medical men at all acquainted with the subject who will deny that in some districts at least contract practice has become in some form or other an absolute necessity. This is abundantly evident from the answers given by 69 divisions of the British Medical Association to whom the question was addressed. Of these 69 divisions 63 unhesitatingly affirmed that in some districts at least contract practice is necessary. Five divisions gave a rather hesitating assent, while only one regarded it as unnecessary. Some of us may heartily dislike contract practice, and while readily admitting that medical attendance is more satisfactory in those districts where no contract practice is required, yet I hold that to a verdict like this we must unhesitatingly submit if we are to be loyal to the best interests of our profession. And, further, it has become plainly evident that the charitable public, many of whom take an intelligent interest in the welfare of the working classes, will never abandon the open door of hospital management till we can plainly show them that we are fully prepared in all possible circumstances to provide without hardship for the wants of the labouring poor. If any escape is ever to be found from our present most unsatisfactory position it will not be gained by our wasting time in considering whether contract practice is desirable or not, but in a strenuous and united effort to remedy its abuses and so to regulate its details that it may meet the requirements not only of medical men but of the working classes themselves.

I shall only refer in a word to two forms of contract practice. 1. There is the private club, which has this advantage, that a medical man is his own master, can make his own terms, and include or exclude patients as he thinks fit. To the private club in the village or where two or three medical men in one district are agreed there can be no objection, but when, as in some parts of London, streets are canvassed from door to door and canvassers paid a high premium for new patients it is surely time that private clubs shared the same fate as medical aid associations. 2. Much has been said for and against provident dispensaries. Their rules and methods vary and while readily admitting that in most of them there is much room for improvement I cannot but regard the main principle as sound. Nor can I see that they differ greatly from what many men now prefer—

namely, a public medical service. The main difference seems to lie in the fact that the public medical service is entirely controlled by medical men, while in the provident dispensary the supervision rests partly with the laity. I do not find, however, that where there is a mixed supervision medical men are so enamoured of the details of business that they show any strong desire to do the work which is generally done by lay members. The great difficulty seems to me to lie in the fact that it is only the provident labouring class, skilled artisans, and small shopkeepers who care to join a provident dispensary. The drunkard, the loafer, and the improvident of the working classes, many of whom are in receipt of good wages, will not join a provident dispensary so long as they find they can readily get a medical order from the parish or free attendance at a hospital.

I have said a good deal, perhaps too much, about the symptoms and treatment of the disease. And now one word as to the diagnosis. That, of course, must depend largely on political and social developments which it is difficult to forecast, but you will forgive me for repeating that what the mode of attendance will be in the future may and ought to be decided by medical men themselves. In any case the issue is extremely uncertain. I can well remember how this country was in a similar difficulty after it had determined on compulsory education. Education was made compulsory, but how were the poor of the working classes to pay for it? Had anyone prophesied 20 years ago that within a few years from that date a Bill would be almost unanimously passed granting free education to the child of the millionaire as well as the pauper he would have been regarded as a fool or a madman. I trust you will exercise your usual forbearance and not place me in either category when I say that quite possibly within the lifetime of some of us a Bill will be passed granting free medical attendance on almost the same lines as free education. I have carefully read the speeches in the House of Commons and the arguments adduced for free education. There is not one of these arguments that could not be urged with as much or even greater force in favour of free medical attendance. Education was made compulsory. Medical attendance is also compulsory. If a child dies in London who has not been attended by a medical man there follows the inquest, in many cases the coroner's censure, and sometimes the imprisonment of the parent. The cost for medical attendance would be vastly less than the cost of free education. The London County Council is expending at the present time about £7 per annum on the education of each child, while the ordinary fee of medical men doing contract practice is 2s. 2d. per annum. I have been credibly informed of one rural district in England where the medical man attends children within a radius of six miles for 8d. per annum. Further, even as regards medical attendance, the trend, as we have seen, is in a socialistic direction. We have seen how at Lambeth and elsewhere the attendance not only on paupers but on the poor of the labouring classes is thrown on the rates. We see it in the hospitals for infectious diseases, where the cost not only of medical attendance but of board and lodging for rich and poor is also thrown on the rates. We see it in the proposal to municipalise hospitals. A bad day you say it will be for medical men when a Bill for free medical attendance is passed. A bad day it may be for the country in general, just as some of us may possibly think it was a bad day for the country when free education was granted, and there now follows in its wake the demand for free breakfasts and much else. I am not at all sure that it would be a bad day for medical men. Without any great entrenchment on rates or taxes medical men practising in some of our poorest districts might not be sorry to have a guaranteed minimum of at least £300 a year, while, of course, the wealthy, and many of the professional and middle classes, would still prefer to pay their medical attendant just as they prefer to pay for their children at school though they could readily avail themselves of free education. I must apologise, however, for speaking of what is not yet within practical politics and is possibly outside the region of profitable discussion. If, however, there is any medical man here interested in the matter I would be glad to discuss it with him privately.

AMERICAN TINNED MEAT.—At a meeting of the Bath board of guardians held on June 27th it was resolved to supply the inmates of the workhouse with English fresh meat instead of the American tinned meats which were now used. In making this change the contract or tinned meats would be terminated forthwith.

TWO CASES IN WHICH GASTRO-ENTEROSTOMY WAS PERFORMED IN THE COURSE OF OPERATION FOR PERFORATED ULCER.

BY EDWARD WARD, M.A., M.B. CANTAB., F.R.C.S. ENG.,
SENIOR SURGEON TO THE LEEDS GENERAL INFIRMARY.

CASE 1.—On Feb. 24th, 1906, I was asked by Dr. J. Irving of Huddersfield to go over to see, a few miles out, a man, aged 55 years, who at 6.45 that morning had been seized with agonising pain in the abdomen, requiring the use of morphine hypodermically and leading Dr. Irving, who knew the previous history, to conclude that the symptoms must be due to the perforation of a gastric ulcer. When I arrived the morphine had had its full effect and the patient was lying comfortably on his back, free from either pain or sickness. There had been no vomiting since the seizure and the pulse was a little over 80, regular and good. The abdomen was not distended but was still and rigid, and there was some tenderness on handling, most marked in the right hypochondrium. The percussion note seemed of little value but we thought that the liver dulness was certainly not quite absent.

Dr. Irving gave me the following history. For 30 years there had been irregular attacks of abdominal pain so severe as to cause the patient to roll on the floor. There were three or four attacks in the course of a year, the pain and discomfort sometimes lasting for a week. At other times there was pain only after a particular meal and it could be brought on with certainty by errors in diet, such as overcooked fish or strong tea. About 12 or 15 years ago there was a period (two or three years) of improvement while taking pepsine. Later the attacks lasted for a month or six weeks and during the course of one he would lose as much as 25 pounds in weight. A year ago he commenced to vomit and for a month about Easter he vomited large quantities of sour material. He then remained pretty well till December last, when the pain became worse again, recurring more or less every day, and about this time there supervened signs of dilatation of the stomach. Still more recently there had been two or three days' intervals of fair comfort after vomiting about two and a half pints, and washing out the stomach would always afford immediate relief. Three days ago the pain was so severe and prolonged that morphine had to be given hypodermically. Next morning he vomited and then remained comfortable until the sudden attack of overwhelming pain a few hours before I saw him.

I must here say that whatever credit is due for the fact that the operation was performed without delay must be given to Dr. Irving. The patient was so comfortable and the abdominal signs were so inconclusive that, considered along with the pulse and the entire absence of sickness, I should certainly have felt constrained to wait for a time if he had been within easier access; but Dr. Irving was so insistent upon the significance of what he had seen in the early morning that I accepted his view, feeling that at any rate we should find ample indication for gastro-enterostomy if nothing more. The operation was commenced exactly six hours after the onset. Upon incising the peritoneum the escape of gas and characteristic "mutton broth" fluid at once made matters plain. There was a large quantity of fluid which had to be ladled out before the perforation could be seen. It was close to the pylorus which was somewhat deeply recessed and fixed under the liver. It was about three-eighths of an inch in diameter, of the usual punched-out appearance, and there were widespread thickening, induration, and puckering of the walls of the stomach and duodenum. With great difficulty four sutures of stout Pagenstecher thread were placed very widely, infolding about three-quarters of an inch on each side of the opening and placing the ulcer at the bottom of a steep gutter, any attempt to approximate the opposite faces of the gutter by tightening the sutures resulting in an obvious tendency to cut through, as had also an attempt to use a closer stitch with finer thread. But leakage was arrested and we had to be content. It was clear, however, that the procedure had practically closed the pylorus and that gastro-enterostomy would have to be done. More fluid

was removed by ladling with the hands as before and when the transverse mesocolon was exposed the posterior operation was performed according to the method of my colleague, Mr. H. Littlewood. Then I passed my left hand down towards the pelvis and using the forefinger as a guide I thrust the knife through the abdominal wall immediately above the symphysis pubis, and introduced a glass drainage-tube into the recto-vesical pouch. The upper wound was closed without drainage and all the fluid which could be removed was withdrawn by syringe through the tube. After the dressing was applied the patient was placed in bed propped almost upright. He bore the operation very well, but liquor strychninæ (10 minims) was given hypodermically with instructions that half this dose was to be added to each enema of a half pint of normal saline solution every four hours.

The after-course was uneventful. On March 21st Dr. Irving wrote to me as follows: "There was no pain and no sickness. At the end of 48 hours there were indications of cardiac failure, which passed off on laying him flat on his back. After 60 hours the drainage-tube was replaced by a gauze wick for 12 hours, upon the removal of which the opening closed and the wound began to heal. There was never any feeling of sickness and warm water was allowed freely from the first. The patient dictated a long letter on the fourth day and took up various business matters with his secretary on the sixth. The only difficulty was in restraining his appetite, as he felt so hungry. The wound is soundly healed." This patient has resumed his ordinary activities and is now quite well in every respect, having entirely lost all his stomach discomforts.

The following notes of the other case are extracted from the reports of the Leeds General Infirmary.

CASE 2.—The patient, a man, aged 39 years, was admitted by me from the care of Dr. W. Kemp of Castleford on April 24th, 1902, in a condition of collapse. The history, which was obtained later, was as follows. About two years before admission he became subject to pain in the stomach coming on half an hour after food and subsiding after retching and vomiting. This pain gradually became more severe and in spite of treatment he grew worse and worse and steadily lost flesh. Six weeks previously he became unable to work owing to pain, vomiting, and weakness, and shortly after leaving off work he had a severe attack of hæmatemesis, vomiting a large quantity of dark blood after the exertion of taking a walk. He became very faint and was put to bed. Under restriction to milk and water, with ice to suck, the hæmorrhage did not recur and in a fortnight he was able to get up but did not resume work. At about 1.30 on the morning of the day of his admission to the infirmary he was suddenly seized with violent pain in the abdomen, which seemed to radiate from the umbilicus and soon became insupportable. He got out of bed, but although he felt very sick he was unable to vomit. He was put back to bed in a cold sweating collapse, and his medical man came and prescribed an opiate, with hot applications to the abdomen. When seen again at 10 A.M. he was no better and Dr. Kemp, diagnosing perforation of a gastric or duodenal ulcer, communicated with me with a view to his admission to the infirmary, where he was received later in the day and was taken at once to the operating theatre, no report being taken of his condition beyond a brief note that he was in a state of extreme collapse, with a slightly distended rigid abdomen, dull in the flanks and resonant over the liver area. He was in a profuse cold sweat and had a feeble running pulse of 150. Chloroform was administered and the abdomen was opened by a median incision from the tip of the ensiform cartilage to the umbilicus. A considerable œdema of the subperitoneal tissue, glistening and watery-looking, was noticed, and upon incising the peritoneum gas escaped, along with a large quantity of dirty-looking fluid, flocculent, but not containing any recognisable fragments of food and with no particular odour. There was readily seen a circular opening about three-eighths of an inch in diameter on the anterior upper surface of the duodenum, well beyond the pylorus and almost inaccessible recessed under the liver. Around the sharply cut, punched-out opening was a wide zone in which the intestinal wall was thick, leathery, and rigid, white and scarred. By means of a long needle-holder the opening was with considerable difficulty closed by Lembert's sutures passed very widely. When this was completed it was seen that the infolding of the stiffened tissues had occluded the duodenum and it became clear that gastro-enterostomy would be necessary.

This was performed by the anterior method, no attempt being made to cleanse the parts, which were swamped in the escaped fluid, as the patient's condition was so critical that any prolonged or formal toilet of the peritoneum was out of the question. Drainage was provided by the introduction of a glass tube into the recto-vesical pouch through a small median incision above the pubes, rapidly made by thrusting the knife through the abdominal wall on to the left forefinger passed down within. The upper wound was then sutured, with gauze drains introduced towards the kidney pouches, and the patient was put to bed in the sitting position. After a few critical days he eventually made a good recovery and has since been heard of as a public-house cadger, apparently able to dispose of alcohol in quantity without inconvenience.

I have related these two cases partly as instances of gratifying and unexpected recovery from a very complicated and unpromising condition but mainly for the purpose of illustrating the uselessness of elaborate peritoneal toilet provided that adequate drainage is established. It is now more than six years since I washed or sponged out the general peritoneal cavity, and although I have seen many cases in which I am firmly convinced that to have done so would have finally destroyed the patient's slender remaining chance of recovery, I cannot call to mind a single case in which I have thought that it would have turned the scale in his favour.

Although I do not suggest that this practice is either original or in any degree uncommon, I still hear and read from time to time of cases in which it has been considered desirable to wash out the general peritoneal cavity with salt solution and now and then I hear of a patient surviving the procedure. I was led to my present uncompromising attitude on this point accidentally and by force of circumstances. I was asked by my colleagues, Dr. T. Churton and Dr. T. W. Griffith, to operate upon a young woman in whose case they had made a diagnosis of perforated gastric ulcer upon all the necessary indications. I found free gas and a large quantity of the dirty "mutton-broth" fluid but I never actually saw a perforation, for the patient, who was most desperately ill, at this stage became apparently moribund and I was told she would certainly not survive to be removed from the table if the operation was prolonged for more than a minute or two. I therefore at a thrust transfixed the abdominal wall above the symphysis pubis, passing down the left hand to assure myself that the bladder was out of the way. A Bantock's tube was passed into Douglas's pouch and the patient was sent back to the ward to die. However, as she rallied a little she was propped up into a sitting posture so that any fluid still escaping from the unclosed perforation might find its way out as speedily as possible through the drainage-tube. There was a profuse discharge at first which gradually diminished and ceased. Although for more than a week this patient seemed hopelessly ill, she eventually, to our great surprise, recovered, and since that event I have never performed any general peritoneal toilet.

Some of my cases of perforated gastric ulcer have been operated upon in very unpromising condition after discouragingly long intervals, and although it is of course impossible actually to prove anything of the kind I am firmly persuaded that the remaining shadow of a chance would have been extinguished if they had been subjected to the further exhaustion of a more prolonged operation and to the shock of a more or less sudden and violent inundation of the peritoneum by a large quantity of fluid of whatever character. I am sure that amongst these cases many lives have been saved by intravenous infusion; I am a convinced believer in the value of strychnine; enemata of salt solution given by half-pints every four hours, or up to the full tolerance of the rectum; and for distension the turpentine enema. I think that a great deal of quite unnecessary torment is caused by this incomprehensible nigardliness in the matter of drink which dies so hard a death, for I fail to understand why a securely sutured stomach cannot be trusted to deal with a little plain water or other bland fluid when we see how constantly it safely disposes of considerable quantities of far more undesirable and presumably noxious material. In many hospitals it appears to be part of a general ritual which ordains that all patients after operation shall be subjected to a torment of thirst for 24 hours at least, or at the most to tantalising teaspoon sips which almost aggravate their distress.

Leads.

A CASE OF CYANOSIS WITH POLYCYTHÆMIA.

By JAMES W. RUSSELL, M.A., M.D. CANTAB.,
F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE BIRMINGHAM GENERAL HOSPITAL.

THE following case is published as a contribution to the study of the polycythæmic condition. The presence of cardiac symptoms, together with the absence of certain enlargement of the spleen, renders it doubtful whether the case can be claimed as one of splenomegalic polycythæmia, though there are certain features which point in that direction. The patient, a girl in domestic service, aged 21 years, was sent to the out-patient room of the Birmingham General Hospital by Mr. L. S. Tomkys of Lichfield on June 29th, 1905. She complained of shortness of breath and swelling of the legs. She was markedly cyanosed and a blood count showed a large excess of red corpuscles. I admitted her into the wards under the care of Dr. T. Stacey Wilson, who kindly placed her under my care, and I have since had her under observation at the Jaffray branch hospital. The family history contains little of importance. Her father committed suicide at the age of 62 years and her mother was found dead in bed, aged 54 years. Three brothers and four sisters are alive and in good health. Two brothers died in infancy and one in later life after amputation of a leg for injury. As a child she was able to play and to take exercise as other children. When seven years of age she had scarlet fever but there is no recognisable history of the occurrence of nephritis. From this time, however, she appears to have been in delicate health; she never passed beyond the fourth standard at school and gives as a reason for her backwardness irregularity of attendance due to frequent illness. She has never had rheumatic fever or other joint affection. Menstruation began at the age of 17 years and has generally been irregular. She has not menstruated at all for the last 18 months. She considers that the present illness began about four years ago when she first complained of shortness of breath on exertion. For the past year her legs have been swollen at intervals and she has noticed a dusky and swollen appearance of the face and eyelids. She has had occasional attacks of slight præcordial pain and has been subject to "fainting fits" after exertion in which she has lost consciousness and occasionally passed urine.

On admission the patient's face was of a dusky bluish colour and appeared somewhat swollen. The conjunctivæ were slightly oedematous and showed numerous groups of remarkably large and tortuous vessels. With the exception of the lips the mucous membranes were not cyanosed, but the skin of the hands and feet was dark red in colour and there was a slight tendency to clubbing of the fingers. Over the trunk were numerous scattered pigmented spots for which no origin could be assigned. The respirations were increased in frequency and the patient became short of breath on any exertion. The heart was somewhat enlarged. The impulse was in the fifth space, slightly outside the vertical nipple line, and the upper limit of the deep cardiac dullness extended into the second left space, in which position were felt a slight diffuse pulsation and a shock synchronous with the closure of the aortic and pulmonary valves. At the apex there was a short systolic murmur, hardly to be traced outwards and not heard at the angle of the scapula. The second sound was clear at the apex but reduplicated and accentuated in the pulmonary area. There was no murmur at the base. The pulse was 120 on admission, small, and of low tension, but with rest it quickly fell to 78 or 80. The blood pressure was not estimated until August 25th when it registered 115 millimetres of mercury. The edge of the spleen could not be felt, even at the end of a deep inspiration, but its dullness extended forwards into the axilla and appeared to merge into that of the left lobe of the liver. The liver dullness began at the upper border of the sixth rib in the nipple line; its edge could just be felt on deep inspiration. The lungs were normal on examination. There was no enlargement of the thyroid or lymphatic glands. The urine varied in quantity from 20 to 40 ounces in the 24 hours. On admission the specific gravity was 1014 and it contained 0.1 per cent. of albumin and

1.3 per cent. of urea. Under the microscope a few hyaline and granular casts were seen with renal and bladder epithelium. On July 9th the albumin measured 0.05 per cent. and the total quantity of urea passed in the 24 hours amounted to 140 grains. On August 6th, after centrifugation, no casts were discovered. The optic discs showed considerable blurring of the edges, obviously due to oedema. In the right disc the veins were greatly enlarged and very tortuous; the arteries were also large. The outer part of the disc showed a very remarkable group of small arterioles and enlarged vessels were seen scattered about the retina. Near the macula was a small patch of pigment, which Dr. D. C. Lloyd Owen, who kindly examined the discs, informed me was the result of former choroiditis. The left disc showed similar appearances but to a much slighter degree. The blood counts were as follows:—Red corpuscles: June 29th, 7,000,000; July 1st, 8,045,000; 19th, 7,900,000; 22nd, 6,812,000; August 5th, 7,518,750; 19th, 6,297,000; Sept. 8th, 8,650,000; and Oct. 2nd, 8,825,000. White corpuscles: June 29th, 7000; July 1st, 7000; and 22nd, 5600. The hæmoglobin was estimated on July 22nd by Oliver's hæmoglobinometer and was much in excess of the limit of the scale, which registers up to 120 per cent. Three differential counts of the white corpuscles were made with the following results:—Polymorphonuclears: July 1st, 74 per cent.; 22nd, 61.4 per cent.; and 29th, 70.5 per cent. Lymphocytes: July 1st, 19.3 per cent.; 22nd, 29.4 per cent.; and 29th, 20.0 per cent. Large mononuclears and transitionals: July 1st, 6.3 per cent.; 22nd, 7.3 per cent.; and 29th, 7.9 per cent. Eosinophiles: July 1st, 0.2 per cent.; 22nd, 1.9 per cent.; and 29th, 1.6 per cent. No abnormality in the size or shape of the red corpuscles was observed during any of the differential counts and no nucleated red cells were seen. On one occasion two myelocytes were noted in a prolonged count. No estimation was made of the viscosity of the blood but Mr. J. Priestley Smith on three occasions examined the blood with regard to its coagulability by a method which he has not yet published. He gives me the following note: "The method employed aims at measuring, not the time necessary for coagulation, as in Dr. Wright's method, but the force required to break the clot when it is fully formed. The blood is of measured quantity, is placed between two surfaces of ground glass, the one plane, the other of known curvature, and is protected from evaporation. In the case here described the breaking force was greater than that of normal blood. It was, however, much less than that which I have found in leucocythæmia. The method is as yet, I think, too new to justify publication of details." With rest in bed the cardiac symptoms improved. Within a few days the oedema disappeared and it did not return on getting up. The cardiac enlargement slowly diminished and by the beginning of August the impulse was within the nipple line, though the upper limit of dulness still extended into the second space and the pulsation and diastolic shock remained noticeable in the pulmonary area. A faint apical systolic murmur was still to be heard on the patient's discharge from the hospital. As shown by the above blood counts the polycythæmia diminished with the improvement in the condition of the heart but it did not disappear. The count of 8,650,000 on Sept. 8th was the first made after the patient's transference to the Jaffray Hospital, which is situated some three and a half miles from the General Hospital. The journey was made in an ambulance and involved no fatigue and the patient had been walking about the ward for some time before her removal. I doubt, therefore, whether the high count can be attributed to the effects of the journey. This and the last count were not made by myself. With the marked improvement in the cardiac physical signs there was no recognisable change in the cyanosis or in the engorgement of the conjunctival and retinal vessels.

In endeavouring to arrive at a conclusion as to the nature of the polycythæmia there is much to be said in favour of regarding it as merely an accompaniment of the cyanosis due to weakness of the cardiac muscle. Although in the hitherto published cases of splenomegalic polycythæmia slight enlargement of the heart has occasionally been noted and in several cases there has been a soft apical systolic murmur, yet, with one exception, none of them has shown any definite symptoms of cardiac incompetence. The one exception is to be found amongst the seven cases published by Türk,¹ but as there was here advanced chronic

nephritis with symptoms of heart failure I should be inclined to doubt the advisability of including the case in the above-named group. The age of my patient is perhaps a little against the diagnosis of splenomegalic polycythæmia, only two of the recorded cases so far having occurred in patients under 30 years of age and 24 being the age of the youngest. The magnitude of the polycythæmia is no reason for denying it a cardiac origin, for Dr. G. A. Gibson² has recorded one case of mediastino-pericarditis with a red cell count varying from 8,000,000 to 8,800,000, and one case of chronic bronchitis and emphysema with mitral incompetence, and another of pure mitral incompetence, in each of which the red cells numbered 7,500,000 to the cubic millimetre. It is to be noted, however, that in the first two of these three cases the polycythæmia completely disappeared with the cessation of the cardiac symptoms; the result of treatment is not noted in the third case. In my case, although the signs and symptoms of cardiac incompetence nearly disappeared, the polycythæmia still persisted at the time of the patient's discharge from the hospital though in a lesser degree than on admission, and the remarkable appearance underwent no alteration. In addition to the persistence of the polycythæmia the curious dilatation of the conjunctival and retinal vessels and the pigmentation of the trunk are in favour of the alternative diagnosis. The differential white cell count is, on the whole, in accordance with that found in most of the splenomegalic cases, though the percentage of polymorphonuclear leucocytes is not quite so high as that generally noted. No normoblasts were seen at any time, whereas in many, but not all, of the splenomegalic cases a few of these cells have been observed. Much weight can hardly be attached to the presence of the two myelocytes seen on one occasion but, as far as it goes, this fact tends to connect the case with the splenomegalic group. As already stated, there was no marked enlargement of the spleen in my case but a similar absence of enlargement has been noted in two of the published cases of splenomegalic polycythæmia.

I have assumed in this discussion that the latter condition is a "definite clinical entity," to use the words of the Editors of THE LANCET in a note preceding my paper published in that journal on Feb. 22nd, 1902. This assumption is disputed by Dr. Gibson, who is inclined to regard the condition as merely one secondary to cardiac weakness. But the case under Dr. R. Saundby's care published in that paper was so entirely free from symptoms of heart weakness and the clinical picture was so totally unlike that of any cardiac case that I have seen that I cannot feel any doubt that it must have another pathology. At present Dr. F. Parkes Weber's explanation of the condition as due to an "increased erythroblastic activity involving a great part, but not necessarily the whole, of the bone marrow," seems likely to hold good. At all events, no other satisfactory theory has been proposed.

Birmingham.

A CASE OF HÆMATOMYELIA DUE TO TRAUMA,

WITH OBSERVATIONS ON THE COURSE IN THE SPINAL CORD
OF THE SECRETORY NERVES TO THE SWEAT GLANDS.

BY W. A. REES, M.B. LOND., F.R.C.S. ENG.,
REGISTRAR AND PATHOLOGIST AT THE BOLINGBROKE HOSPITAL.

HÆMATOMYELIA is the term used for hæmorrhage into the grey matter of the spinal cord. The hæmorrhage is due to trauma in 90 per cent. of the cases and is caused by fracture or dislocation of the vertebræ in some cases; in others the injury may give rise to hæmorrhage in the grey matter without any actual lesion to the bony canal. In all of Thorburn's cases the hæmorrhage occurred at the level of the fourth, fifth, and sixth cervical vertebræ, and he considers it probable that the hæmorrhage is usually produced by a partial dislocation with recoil. The hæmorrhage takes the form of a cone, or rather of two cones, tapering off upwards and downwards and extending over a considerable length of grey matter. This spread of the hæmorrhage

¹ Wiener Klinische Wochenschrift, 1904, Nos. 6 and 7.

² Abstract of a paper read before the Royal Society of Edinburgh, THE LANCET, Jan. 17th, 1903, p. 155.

through the grey matter around the central canal is due to the blood tracking along the line of least resistance, for experiments in animals have shown that fluids injected into the spinal cord tend to find their way into the grey matter and spread through it in preference to the white matter. Hæmatomyelia is not so very uncommon—five cases were admitted into the Manchester Royal Infirmary in three years—and the condition is liable to be mistaken for one of simple crush of the cord unless the symptoms are carefully investigated. The hæmorrhage in the following case probably started at the first dorsal segment of the cord, producing its maximum effects at this level, but it also spread upwards to the fourth cervical and downwards to the third dorsal spinal segments.

The patient, a brewer's drayman, aged 42 years, was admitted into the Bolingbroke Hospital on August 30th, 1905, under the care of Mr. H. Burrows. He was being driven along in his dray when he slipped and fell out over the back of the cart. He turned a "somersault" as he fell and struck the back of his head and shoulders on the ground, the head being forcibly bent forwards on to the chest at the same time. He felt something go "click" at the back of his neck but was not stunned at all by the fall and was immediately helped on to his feet. He was quite positive that he was able to use his legs and even to stand with support immediately after the accident but within a few minutes he felt a numbness spreading downwards from the trunk to the lower limbs and in about five minutes the legs were completely paralysed. He was admitted into the hospital about half an hour after the accident.

On admission the patient was a healthy-looking man, very tall and strongly built; he was quite sober and could give a clear account of the accident. There was a small abrasion on the back of the head but no deformity or irregularity about the spine. The third dorsal vertebra was tender on firm pressure. The pupils were equal and reacted to accommodation and light. Both arms were weak and as he lay in bed he could only just manage to raise his hands to his mouth. The lower six intercostal muscles, the abdominal muscles, and the muscles of the lower limbs were completely paralysed, respiration being carried on by the diaphragm only. Sensation was unimpaired in the head, the neck, and the arms, except for the skin over the little and ring fingers of each hand where there was considerable numbness. On the front of the chest sensation was normal above the level of the nipples, while below this level the sense of pain and temperature was absent. The upper limit of this "dissociation of sensation" was variable: thus on tracing out the area for anaesthesia to pain with a prick of a pin from above downwards the prick could be perceived as a painful sensation as low as the level of the fifth rib in the nipple line, while in the reverse direction the prick did not cause any pain till the level of the third rib was reached. The lower limit for perception of temperature varied equally and was at a slightly higher level on the chest wall than that for the sense of pain. On the back sensation was normal at the level of the first dorsal vertebra; from here to the sixth dorsal vertebra the sense of pain was present but was blunted (thus the patient could not distinguish between a prick and a pinch); from the sixth dorsal vertebra downwards there was no perception of pain or temperature. All over both legs the dissociation of sensation was well marked, the very lightest touch being distinctly felt. The knee-jerks were present on admission but disappeared completely by the third day to reappear again at the end of the first week, and by the tenth day from the accident they were markedly exaggerated. Priapism and turgidity of the penis were noted. The urine was retained and the motions were passed involuntarily.

By the fifth day after admission voluntary power in the arms had returned completely. At first the patient complained of a severe gnawing pain in both elbows in the neighbourhood of the internal condyle. There was no local lesion here and the pain seemed to be a referred pain along the ulnar nerves from the spine. A good deal of pain in the back of the neck was experienced also. A catheter was passed twice daily for five weeks, by which time, owing to the return of power in the abdominal muscles, he was able to empty his bladder naturally. The occurrence of cystitis was prevented by careful cleansing of the penis each time the catheter was used and by wrapping the organ in an antiseptic dressing in the intervals; in addition urotropin was given from the beginning as a prophylactic. After six weeks there was slight return of voluntary power in the legs, but by this

time the legs were becoming very spastic and splints had to be used to correct the tendency to flexion and adduction. During the first week there was a passive serous effusion into both knee-joints which showed a tendency to recur later; this may have been a trophic change comparable to the joint affections of syringomyelia. At the end of two months there was marked atrophy of the muscles of the thenar and hypothenar eminences and the interossei of both hands.

The man was discharged from the hospital on Nov. 24th. He was readmitted on Feb. 9th, 1906, because the flexion deformity of the legs had greatly increased; painful spasms preventing sleep occurred in the legs at frequent intervals and the knees could not now be straightened beyond a right angle and had become so pressed together by the spasms of adduction that a large sore had formed over the inner condyle of the right leg. There were several sores on the posterior surfaces of the legs, caused by the splints which had been employed ineffectually to correct the deformity. Under chloroform the inner and outer groups of hamstring muscles were tenotomised and the legs were forcibly straightened and fixed on a Thomas's double extension and abduction frame, the abduction being about four feet at the level of the ankles. Owing to the over-stretching the adductor muscles became quite powerless and the adductor spasms ceased at once, and the flexion spasms were rendered very slight and occasional; the patient experienced great relief from the first and was able to sleep again. He was kept on the frame for a fortnight and then it had to be omitted owing to the formation of pressure sores; the knees now could be kept straight by means of short back-splints and the power in the legs was much improved; the right leg could be raised off the bed and abducted and adducted at will so long as the knee was kept straight by a back splint. This method of over-correcting deformities produced by paralysis is especially useful in spastic paralytic conditions, as in addition to preventing the occurrence of the spasms it allows the weakened opposing muscles to regain their tonicity and power and the general effect on the strength of the limb is most marked. The great difficulty in these spinal cases is the formation of pressure sores and with every care these are nearly bound to occur; still the benefits derived from the use of the frame quite outweigh this disadvantage.

Remarks.—The presence of the reflexes on admission is interesting; it may perhaps be explained by the fact that the hæmorrhage had not finished extending as the case was seen so soon after the accident; later by the third day the hæmorrhage had produced its maximum effect and the reflexes were consequently entirely abolished. At the end of the first week the reflexes reappeared and became exaggerated, as is usually the case when the lesion is well above the lumbar enlargement.

No spinal myositis was observed in this case; it may have been overlooked, as Thorburn considers this symptom nearly a *sine quâ non* in hæmatomyelia; on the other hand, Gowers in an account of the affection in his "Diseases of the Nervous System" does not even mention this symptom.

The dissociation of sensation was present and well marked and continues at the present time, seven months after the accident, though it is not now so definite as at first. The level of the anaesthesia on the front of the chest pointed to the lesion not reaching the fourth cervical segment of the cord, for the descending branches from the third and fourth cervical nerves to the skin of the upper two or three intercostal spaces were unaffected. The fact that sensation behind extended very much lower than segmental appearances would lead one to expect is difficult to explain but is almost universally met with (Thorburn).

Bed-sores proved a most troublesome complication; the heel could not be left in contact with the bedclothes unprotected by wool for an hour without blistering, and if the patient was rolled over on to his side a sore would form over the great trochanter in a very short time in spite of water beds and other precautions. We see, therefore, that it is not the posterior columns of the cord which convey the trophic nerves to the skin, for these were undamaged in this patient, but it is the grey matter which controls the nutrition of the skin.

The diagnosis of hæmatomyelia rests on the suddenness of the onset of the symptoms after the accident; in this case it was only a matter of minutes, in Dr. S. J. Sharkey's case¹ it was three hours and this would probably be the outside limit. There are no initial spasms and rigidity as in spinal

¹ THE LANCET, Oct. 31st, 1891, p. 973.

meningeal hæmorrhage, which also takes longer to develop. No initial fever is present as in myelitis, a point which is of great importance in diagnosing between the non-traumatic cases of hæmatomyelia and myelitis. The dissociation of sensation is most characteristic and distinctive of the disease. The atrophy of groups of muscles, in this case of the small muscles of the hands, points to a central destructive lesion in the grey matter of the anterior cornua. The site of the lesion also—namely, in the lower cervical region—is characteristic.

The prognosis is better than could be expected from the initial severity of the symptoms; if the patient gets over the immediate dangers of bronchitis, cystitis, secondary myelitis, and bedsores he gradually recovers some power in the legs and the process of improvement extends over a period of a year or more.

Observations on the course of the secretory fibres to the sweat glands.—The following observations with regard to sweating were made on this patient at the end of the first week after the accident. An injection of pilocarpine nitrate (one-fifth of a grain) was given subcutaneously and was followed by a further injection of one-sixth of a grain in half an hour. Sweating was produced all over the body but was most marked on the lower limbs and trunk below the level of the nipples. On the next day the patient was given a hot-air bath in the ordinary way, the hot air entering from the foot of the bed and passing over the legs and then over the rest of the body. After 20 minutes sweating occurred which was distributed over the body as follows. The head, which was necessarily not included in the bath, neck, arms, and upper half of the chest sweated profusely; the lower half of the chest and upper part of the abdomen were only just moist; while the rest of the body below the level of the iliac crests was quite dry. At the same time there was a rise in body temperature of two and a half degrees.

These simple observations, I think, raise the following points in regard to the nervous mechanism of sweating in the human subject. They were carried out at the end of a week after the injury, as by then the vessels supplying the paralysed parts ought to have recovered their tone and the initial vaso-dilatation should have subsided. In the first observation the increased sweating in the paralysed parts is due to the uncontrolled action of the pilocarpine on the cells of the sweat glands in these parts. This effect has been used by Victor Horsley and others to determine exactly the upper limit of a spinal lesion, especially before an operation is performed for the relief of pressure by laminectomy; it is also useful as a means of distinguishing functional paraplegia with anæsthesia from organic disease. The object is much better attained by means of the second method, which allows comparison to be made between the absolute dryness of the skin in the paralysed parts with the profuse sweating present in the unaffected region.

In animals there is a subsidiary sweat centre in the lumbar enlargement of the spinal cord, for if in the cat the spinal cord be cut across above the exit of the twelfth thoracic nerves and the animal exposed to hot air (60° to 70° C.) for from five to ten minutes sweating still occurs in the hind limbs (Luchsinger). On the other hand, in man there is no positive evidence of the existence of such a centre in the lumbar cord; in the cases of injury to the cord where the sweating has been recorded there has always been an interference with reflex sweating, as in this case. The lumbar sweat centre may, however, have had its excitability so depressed by the injury that no reflex sweating could occur; in animals the experiment does sometimes fail, probably from this cause. The mere fact that reflex sweating does occur in animals is positive evidence for the presence of a sweat centre in the lumbar cord in animals, while the fact that reflex sweating has not been observed in man is negative evidence as far as it goes against the presence of a sweat centre in the lumbar cord in man. The abolition of the reflexes at first after a spinal injury points to the general depression in the excitability of the cord but in this instance the experiment was carried out at the end of the first week at a time when the reflexes were returning and becoming exaggerated and therefore the spinal sweat centre, if it had existed, should no longer have had its excitability lowered by the accident. We want, however, further clinical evidence on this point, as the cases where any record of the sweating below a spinal lesion has been kept are too few to allow one to dogmatise on the point. If it is granted that the lumbar sweat centre is non-existent in man, then normally sweating is produced by impulses conveyed to the periphery by secretory nerve fibres which pass

down the cord from the sweat centre or centres situated in the medulla or upper part of the cord; the passage of these impulses was interrupted in this patient by the hæmorrhage in the cervical region into the grey matter round the central canal. This fact affords, therefore, some evidence that the secretory fibres for the sweat glands pass down the spinal cord in the grey matter. The rise of two and a half degrees Fahrenheit in the body temperature showed how the heat-regulating apparatus is put out of working order in these cases of spinal injury.

I am indebted to Mr. Burrows, under whose care the patient was while in the Bolingbroke Hospital, for leave to publish these notes.

Bolingbroke Hospital, S.W.

MOTOR-DRIVER'S SPINE (?).

By W. J. BURROUGHS, M.R.C.S. ENG., L.R.C.P. LOND.

THAT the list of diseases depending for their causation upon the occupation of their victim is already a lengthy one few will question. Doubtless, also, as such occupations increase so in like manner will the diseases arising therefrom. The case the details of which I subjoin is probably yet another addition to the already considerable total and may possibly prove of some degree of interest when viewed in that light.

The facts are as follows. On the morning of April 4th last I was called to a strong, healthy-looking man, of fine physique, who informed me that his work was that of a motor omnibus driver. His age, he stated, was 34 years, his height was six feet, and his weight was 14 stones. His father, previously a healthy man died at the age of 59 years from some acute form of diarrhoea which was neglected. His mother, aged 70 years, had always been, and still is, a healthy woman. He had, too, he said, one sister, aged 29 years, who had always enjoyed excellent health, as she does at the present time, and two brothers who died in early infancy, the cause of their decease in either instance being unknown to him. Personally, the patient said that he had always been a very healthy and temperate man, a fact borne out by his personal appearance. He had never suffered from any venereal disorder, neither was there any history of external injury to account for his present condition.

On the day previous to his illness (April 3rd) he began his work at 3 P.M. and continued to 12 midnight. The engine he drove was a 30 horse-power Mercedes. I merely mention this fact as an engine of such horse-power requires a very considerable amount of physical energy to start it and in an ordinary way it is set in motion in the morning and does not require restarting all day but is simply connected or disconnected as movement or the reverse is required of the vehicle. On this particular day, however, a certain portion of the mechanism acted badly and caused the engine to stop a considerable number of times and on each occasion it had to be restarted by the patient. Whether on this account or on that of the extra vibration produced by the defective working of the machinery, he appeared to have felt more than usually exhausted on his return home and on the following day his condition was as follows. His facial expression was one of anxiety and he was obviously in a highly nervous state, getting easily excited. He complained of persistent acute pain which he referred to the right hip and which became so intensified by pressure that he was unable to lie on that side. He also noticed a dull aching pain across the loins, more pronounced on the right and, further, that he was unable to move the leg of this side, which he described as being so painful that he could scarcely bear the weight of the bedclothes upon it. Owing to the tenderness of the right hip and back he found the position of the greatest ease either in resting upon his left side or in an attitude of semi-pronation.

On examination his pulse was 75, his respirations were 20, and his temperature was 98.6° F. (no temperature higher than this was recorded throughout). His pupils were equal and reacted to light and there was no loss of accommodation. Tenderness on pressure was experienced to the right of the third and fourth lumbar spines, extending outwards for about six inches over an area about three inches wide. The whole of the right leg was in a state of spastic rigidity. Both

the hip and knee of this side were very slightly flexed but any attempt at further flexion or extension caused considerable pain. There were no bladder or rectal symptoms. The patellar reflex in both legs was exaggerated but much more markedly on the right side and on both its production caused shooting pain referred to the lumbar region. The skin of the whole of the right leg was hyperæsthetic, this state being more pronounced upon the inner surface of the limb. The drawing of the pulp of the fore-fingers slowly up the sole of the right foot caused great pain and the same action conducted quickly made the patient cry out loudly and draw up the foot, an action he was quite unable to accomplish voluntarily. Ankle clonus could not be obtained. The condition of the left leg apart from the increased knee-jerk was practically normal. On the following day (April 5th) the pain in the hip was slightly less, though its presence had given the patient a bad night. The muscular rigidity had considerably decreased but girdle pain coming on at intervals and starting at a spot corresponding to the third and fourth lumbar spines was complained of. The patellar reflexes were almost unobtainable and the sensation of the right leg was greatly diminished. The pulse, the respiration, and the temperature were normal. On the 6th the knee-jerks of both sides were absent. The rigidity had disappeared and complete anaesthesia of the whole of the right leg with a diminution of sensibility to heat and to cold existed, sensation in the left leg remaining unimpaired. The pain in the hip was considerably better. On the 7th the knee-jerks were still absent. The sensibility of the right leg had returned slightly, the patient with his eyes closed being able to recognise when he was touched, though unable to locate the precise spot or to estimate how many pin-points or how many fingers were placed upon the affected limb at a given time, even when a considerable interval existed between them. The pain in the hip had entirely gone and he had only experienced a slight sensation of girdle-pain at long intervals. The patient was able to move much more freely in bed, but although he was now able to sit up he could not do so for more than a few seconds at a time, as it still caused him pain in the back. On the 8th his condition was practically unaltered but he expressed himself as feeling a little better. On the 9th he showed marked improvement, sensation had almost entirely returned in the affected leg, but the knee-jerk was still absent in both. The action of the pupils continued normal as at first. On the 10th there was a still further improvement, the patient being able to sit up longer and with less difficulty. From this time forward he made an almost uninterrupted recovery, getting up about the 17th and going out of doors about the 24th.

With regard to the treatment adopted the patient was kept chiefly in a semi-prone position, his left side being the lower, this proving to afford the greatest degree of comfort compatible with the requirements of posture in such a condition. His bowels were kept freely opened with aperients, three grains of calomel being given at the outset. During the first ten days of his illness he was kept on a mixture containing ten grains of iodide of potassium and 40 minims of tincture of hyoscyamus to the ounce taken every four hours. The patient bore the iodide well and at no time experienced any disagreeable symptoms beyond slight nasal catarrh. After the first ten days the dose of the iodide was reduced to half and combined with small doses of strychnine together with aromatic bitters. For the first week he was kept on a complete milk diet, no alcoholic stimulants whatever being allowed. The second week he was permitted the addition of beef-tea, Brand's essence of beef, &c. The third week he was placed on a diet consisting chiefly of fish, eggs, toast, and farinaceous puddings, and so by degrees did he progress to his normal food. He was, however, advised to abstain from all stimulants for some time to come. I last saw the patient on May 10th and he had now quite recovered except that the patellar reflexes, although showing considerable improvement, were still scarcely as brisk as they should be.

As to the diagnosis: taking into consideration the very slight alteration in temperature, the irregular grouping of the symptoms, the spastic condition of the right leg, the early change from hyperæsthesia to total loss of sensation and deep reflexes, together with the subsequent recovery of sensation in the continued absence of those reflexes, all appear when collectively considered to point rather to a localised myelitis than to a spinal meningitis, hæmorrhage

into the cord or any of the other conditions which naturally arise in one's mind in such a case. Be this as it may, there seems little reason to doubt that the cause was intimately connected with the conditions under which a comparatively new occupation is conducted, and although I am unprepared to say whether the pathological state produced was the direct outcome of the constant jarring to which a driver of one of these vehicles is exposed or to the excessive muscular effort required of the patient on the particular day on which he developed his malady, the fact of his illness remains and it would be interesting to learn if similar cases have come within the experience of others besides myself.

Oakley-square, N.W.

SOME THROAT AFFECTIONS.¹

By W. H. KELSON, M.D. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON AND PATHOLOGIST TO THE LONDON THROAT
HOSPITAL.

THE time at my disposal this evening is short and I therefore have selected just a few only of the diseases of the throat, picking out those with which I have found men doing post-graduate work are not familiar and which are often confused with other complaints.

Let us take *mycosis*. A patient, most probably an anæmic young woman, though this disease may occur at all ages and in both sexes, comes complaining of a slight pricking or burning sensation in the throat, or perhaps has felt nothing wrong but while contemplating the beauties of her mouth in the looking-glass has noticed white patches on the fauces. On examination you find these white spots or tufts are most numerous on the crypts of the faucial tonsils but are also often found on the lingual tonsil and have been noticed in Luschka's tonsil and downwards so far as the pyriform fossa and vocal cords. On attempting to remove these spots considerable difficulty will be met with and bleeding is liable to occur but the tissues round about are pale and show no signs of inflammation, differing in these respects from the caseous masses of follicular tonsillitis, with which disease it is often confounded but in which the soft material filling the crypts comes away easily. The symptoms of this complaint may be *nil* and but rarely amount to pain; it is almost essentially a chronic disease, its duration extending generally over years, though in rare cases acute attacks have been recorded accompanied with febrile symptoms. If some of the spots be scraped and the material acidified and stained with iodine in iodide of potassium bundles of threads stained blue are found consisting of the leptothrix buccalis and if sections be made the epithelium will be found to be thickened and horny, and, in fact, a process of keratosis has been going on. As to the relationship of the bacteria to the epithelial changes opposite views are held, some believing the leptothrix to be causative, others only secondary and saprophytic.

As regards treatment some authorities consider this affection harmless and advise that it should be left alone so far as local remedies go, only treating the general health if necessary; the greater number, however, consider that local treatment should be undertaken and of the agents employed salicylic acid, alcohol, formalin, and iodine are some of the favourite ones and the galvano-cantery has been extensively used, but to be successful there must be great perseverance as the disease is exceedingly prone to recur. If the tonsils are much affected and hypertrophied tonsillectomy is the best treatment. The spots have been found to disappear after the habit of smoking tobacco has been contracted.

Vincent's angina.—From time to time one comes across cases of ulceration of the tonsil of a puzzling character. The ulcer is covered with membrane and the appearance is somewhat suggestive of diphtheria and the submaxillary glands are generally enlarged; there is, however, but little constitutional disturbance usually though fatal cases in children have been recorded; sometimes the complaint has been confounded with syphilis and even follicular tonsillitis. The duration of the disease is about from one to ten weeks, on an average three. As regards treatment, applications of iodine have been most successful. On removing a portion of the membrane and staining with methylene blue large numbers of a fusiform bacillus are found and these are

¹ A paper read before the Hunterian Society on Feb. 28th, 1906.

believed to stand in a causal relationship to the disease and are known as Vincent's bacilli.

Streptococcal inflammation of the pharynx is not always easy of diagnosis and one may take as a type erysipelas of the fauces. Unfortunately, in hospital practice one sometimes sees typical cases. The patient has a chill and vomits and complains of sore-throat which, on examination, is found to be dry, shiny, and dark-red. The temperature is raised and the submaxillary glands are swollen, and if the patient should be one on whom a mastoid operation has been performed the next day the disease may be found to have tracked up the Eustachian tube and involved the deeper parts of the wound and thence spread over the neck and face.

Chronic pharyngitis presents some interesting points and it is a curious thing that though the state of the tongue has for ages been looked upon as an index as to the condition of the stomach the same stress has not been laid upon pharyngeal conditions, but woe to the medical man who tries to treat successfully chronic pharyngitis without bearing the digestive organs in mind and most beneficial results are obtained by dieting and medicines, such as nux vomica, dilute mineral acids, bicarbonate of sodium, gentian, the salts of magnesia, rhubarb, &c., and prohibiting or limiting the use of tobacco and alcohol. Under the heading of chronic pharyngitis a large number of different complaints are included and these are both common and troublesome and, in fact, our out-patient departments are full of them, and I am sure it would well repay a worker to investigate them more thoroughly. There is one common form in which the chief symptom is pain, often accompanied by irritation, producing hawking or coughing, and which I think may be well described as aching throat. In this affection swallowing is not painful, just the opposite to acute pharyngitis, but, on the other hand, the pain is relieved by taking food. On examination the pharynx may be dry and glazed, at other times it is granular and sometimes looks normal, but none of these seem to be essential conditions, and though the local appearances may often be improved by paints, caustics, and cautery, yet this affection can seldom be cured by these means, and I am inclined to consider the aching rather of a gouty or rheumatic character; one, of course, must see that the teeth are sound, as no doubt the pain is sometimes of dental origin; also one must remember that nature has intended that air should reach the pharynx only after having been purified, warmed, and moistened by the nose, so that if the latter is blocked or otherwise unable to perform its duties properly the pharynx and larynx suffer.

We are all well acquainted with secondary and tertiary syphilitic affections of the throat but there is a disease closely resembling early secondary syphilis of the fauces which, however, is of a different nature and of which I have from time to time shown cases at the Laryngological Society of London. The chief points about it are as follows: (1) the affection runs a chronic course—generally over a year; it is superficial and leaves no cicatrices and is never vesicular but consists of whitish patches on a red ground; (2) it is more or less symmetrical, affecting the tonsils chiefly and the palate; (3) antisyphilitic remedies have no effect and there is no history or other sign of syphilis to be found after careful examination; and (4) it is accompanied by a good deal of burning pain and sometimes disappears almost and then relapses. Arsenic has appeared to be the most beneficial drug in this disease.

Cavendish-place, W.

THE LENHARTZ TREATMENT OF GASTRIC ULCER AT THE EPPENDORFER KRANKENHAUS, HAMBURG.

By J. VICTOR HABERMAN, A.B., M.D.

MUCH is being said at present in German professional circles about the Lenhartz treatment of *ulcus ventriculi* which, though employed at Eppendorf for some years, is comparatively new to the medical world and radical enough to make it a subject for discussion, especially in view of the fact that the results attained at Eppendorf and reports of trials at other German hospitals proclaim it not only theoretically sane but remarkably efficacious in practice.

The dietary treatment generally adhered to in this condition follows the plan based upon the work of Cruveilhier,

Ziemszen, Leube, and Fleiner, with slight modifications in various hands, giving the stomach at first complete rest, allowing nothing per mouth save the sucking of ice, especially after a hæmatemesis, and furnishing nourishment by means of rich nutrient enemata. After several days a milk diet is substituted with strict insistence on small quantities at short and regular intervals allowing only after the second or third week 250 grammes, the maximum for every two or three hours and this course continued for from four to six weeks. Occasionally other fluid foods are permitted, some white meat after the fourth week, red meat in the sixth, and finally and with care the gradual addition of vegetables.

At the Congress for Internal Medicine at Wiesbaden in 1901 Professor Lenhartz strongly protested against this "starvation regimen" and suggested a concentrated egg-albumin diet as a more rational method in the treatment of a gastric ulcer, for probably the chief cause of its persistence is the hyperchlorhydria almost invariably present and, as Fleischer has pointed out experimentally and Riegel substantiated clinically, egg albumin is the most efficient food that will "bind" HCl and thus neutralise the existing hyperacidity. In the hyperacidity occurring in nervous disorders a rich albuminous diet has long since been found the most serviceable medication. And similar to the gastric disorder in neurological subjects is that in chlorotic girls—the epigastric distress, the sour regurgitation, the feeling of pressure and pain after eating, and the hyperchlorhydria here also almost invariably present. We are sometimes undecided whether the hyperacidity pure and simple or an ulcer not yet advanced to a bleeding stage lies behind the trouble. Indeed, not only have these symptoms led to the diagnosis of gastric ulcer but only too frequently has a chlorotic condition been the precursor of such. Here, too, the same indications hold good and, in fact, the treatment of chlorosis by means of such a diet, together with the administration of iron, has met with exceptional results and is the one employed at Eppendorf.

From observations made in an extensive practice at Eppendorf (where 10,000 and some odd number of patients were admitted on the medical side in 1905) Lenhartz concluded that many cases of gastric ulcer do not definitely improve, or but very slowly, under the method of entrenched milk feeding; that the high acidity is not measurably lessened; and pre-eminently this, that if patients are brought into the hospital in a poor physical condition consequent upon one or more hæmorrhages, often indeed in collapse, the "starvation treatment"—the ice and nutrient enemata and insufficient milk feeding following—not only maintains the patient in his wretched anæmic state but may even drag him into serious inanition and such an undermined constitution hardly favours the speedy healing of an ulcer. Moreover, frequent nutrient enemata excite the gastro-intestinal tract into peristaltic activity and may thus induce renewed bleeding; beside, very little nutriment is after all obtainable. On the other hand, should more milk be given by mouth, merely enough to preserve the body weight—three litres for an adult—would overfill the stomach and stretch its walls, thus preventing a contraction of the ulcer and again offering the danger of renewed bleeding. Professor Lenhartz therefore sought another dietary treatment, one that would especially combat the hyperchlorhydria and reinforce the enfeebled and anæmic state of the patient, for such reinforcement is imperative in the severe cases, particularly where hæmorrhage has occurred. And so the concentrated egg-albumin diet was tried. In case after case the effect proved so gratifying that this method became the routine hospital treatment. The result of such treatment is that the sour regurgitation subsides, the vomiting immediately ceases, the pain and distress after eating within a few hours to a few days disappear, and finally an increase in the body weight is manifest as early as the first week. Besides, the improvement is comparatively rapid, so that the patient can be dismissed as cured within a briefer time than formerly.

The following is the tabulated regimen at the hospital: Absolute rest in bed for at least four weeks. All mental excitement to be avoided. An icebag is placed upon the stomach and kept there almost continually for two weeks. This prevents gaseous distension, prompts contraction of the stomach walls, thus tending to obviate hæmorrhage, and eases the pain when present. On the first day, *even where a hæmatemesis has occurred*, the patient receives between 200 and 300 cubic centimetres of iced milk given in spoonfuls and from two to four beaten eggs within the first 24 hours. At the same time bismuth subnitras is given twice or

thrice a day, two grammes *pro dosi*, and continued for ten days. The eggs are beaten up entire (with a little sugar) and the cup containing them is placed in a dish filled with ice so that they remain cold. Sometimes a little wine is added. This food at once "binds" the super-secreted acid and therefore mitigates the pain so rapidly and causes the vomiting, often quite troublesome, to cease. The portion of milk is increased daily per 100 cubic centimetres and at the same time one additional egg is given, so that at the end of the first week the patient is receiving 800 cubic centimetres of milk and from six to eight eggs. Both these foods are now continued in the same amount *pro die* for another week. For reasons given above no more than one litre of milk a day is allowed at any time. Besides milk and eggs some raw chopped meat is given from the fourth to the eighth day usually on the sixth, 35 grammes *pro die*, in small divided doses (easily stirred up with the eggs or given alone); the day after 70 grammes, and later possibly more if well digested. The patient is now able to take some rice or

8 per cent. of the patients, three of whom had at first been in other hands. Among the 135 cases of Lenhartz there were three deaths, one due to severe anæmia (the blood examination showed but 17 per cent. of hæmoglobin on admission), one on the fifteenth day of treatment due to femoral thrombosis and pulmonary emboli, and one on the twenty-seventh day, the necropsy disclosing five ulcers, one having eroded a duodenal vessel thus occasioning profuse bleeding. This patient had had many hæmorrhages before admission. Of the remaining cases the severest gave the most gratifying results. Those whose blood on admission contained but 35 per cent. of hæmoglobin or under showed an average weekly increase of 7.7 per cent.; those having between 35 per cent. and 60 per cent. an average weekly increase of 6.34 per cent. In 25 cases under my own observation during four months there was an average weekly increase in weight of 1.15 kilogrammes. The majority of patients were dismissed as cured before the eighth week. In no case was it manifest that any unfavourable effects were

* From the first to the seventh day inclusively the eggs are beaten; from the seventh to the fourteenth day inclusively half are beaten and half are cooked.

"greisbrei," well cooked, and a few zwieback (softened). In the third week quite a mixed diet is tolerated, the meat being given now well cooked or lightly broiled. All heavy foods are, of course, interdicted as well as vegetables with husks, &c., and those tending to produce flatulence. At the same time the patient is given strict orders to masticate his food thoroughly. The accompanying table gives the daily quantities at a glance.

The bowels are not to be moved, both in order to avoid any peristaltic irritation and to permit the reabsorption of blood that may have passed into the intestine. In fact, one need pay absolutely no attention to constipation in the first week, even in many cases to the end of the second. After the second week the bowels are moved with small glycerine injections or warm water, and after the third week this is done daily if a movement does not occur spontaneously. After this one tries to control the bowels by means of the food and by getting the patient to go to stool regularly.

For the anæmia iron is given in the form of a soft preparation of Bland's pills:

Ferri sulphas, 10.0 grammes.

Magnesia usta, 1.75 grammes.

Glycerinum, gutta, xxx. (3.6 grammes).

Misce et divide in pilulas lx. (Pil. Blandii Lenhartz.)

2 pills to be taken two or three times a day.

These pills are given as early as the sixth, eighth, or tenth day of treatment according to need, administering them at first in a macerated condition. In severe cases arsenic is also given in the form of "Asiatic pills," each containing 0.001 gramme of arsenious acid. These pills are given in gradually increasing doses: three for three days, four for four days, up to seven for seven days, then decreasing again six for six days, &c. After the tenth day and to the sixth week bismuthum compositum is substituted for the subnitras and given three times a day before meals. The patient is usually allowed up on the twenty-eighth day and is dismissed in the sixth to tenth week.

By this method all patients have been treated in the Eppendorfer Krankenhaus for some five or more years, the treatment being at all times begun *at once*. Before the Lenhartz method was employed the records of 100 cases showed a recurrence of hæmorrhage in 20 per cent. of the patients. In a series of 135 cases with one or more hæmatemeses on, or just prior to, admission such recurrence was noticed in but

produced by the treatment. Thus far Minkowski, Albert Fraenkel (Urban, Berlin), Wirsing, and Senator have acknowledged the excellence of the Lenhartz treatment, the last named, however, suggesting some modification.

ST. THOMAS'S HOSPITAL.

AN UNUSUAL CASE OF TYPHOID INFECTION.

(Under the care of Dr. HECTOR MACKENZIE and Mr. W. H. BATTLE.)

FOR the notes of the case we are indebted to Dr. Ronald E. G. Gray, late house surgeon to the hospital, and for the bacteriological report to Mr. Leonard S. Dudgeon.

The patient, a man, aged 28 years, was admitted to St. Thomas's Hospital under the care of Dr. Hector Mackenzie on July 7th, 1902, suffering from typhoid fever. The illness commenced seven days before admission with pain in the back and abdomen, headache, and vomiting. On July 11th perforation occurred and after abdominal section a perforation of the ileum was sutured by Mr. W. H. Battle. On and after August 4th the temperature did not rise above 99° F. and convalescence set in. The patient left the hospital on Sept. 10th. On Sept. 18th he was readmitted for pain in the right femur and knee which was treated with iodide of potassium and local applications and he was able to return home in about three weeks. On Oct. 18th, 1904, more than two years after typhoid fever, he was readmitted, complaining that for the previous four weeks he had had pain of a gnawing

character, worse at night, in the lower third of the right femur. Except for some abdominal pain, which followed an injury whilst carrying a sack of coal, he had been quite well in the interval. On admission the lower third of the right femur was uniformly enlarged and extremely tender on pressure. On Nov. 6th an incision was made by Mr. Battle on the outer side of the thigh above the knee. Thickened periosteum was incised and thick yellow pus immediately sprang into the wound. A bacteriological examination of this pus was made by Mr. Dudgeon and typhoid bacilli were found in pure culture. The patient left the hospital on Dec. 21st, 1904, at which time his wound was soundly healed, but a few weeks later a portion of the scar gave way and a small sinus formed from which there was some purulent discharge. He came to the hospital for treatment in the middle of June, 1905. There was a small sinus situated on the outer side of the right thigh leading down to the bone. The patient stated that he applied a dressing daily at his home but the sinus did not appear to make any attempt to close. At his next visit, a fortnight later, he was in great trouble, as his wife had been admitted to the hospital suffering from typhoid fever. She was admitted to Charity Ward under the care of Dr. W. S. Colman with a severe attack of typhoid fever which proved fatal at the height of the disease. The typhoid serum reaction was positive and at the necropsy severe intestinal ulceration and consolidation of the lungs were seen. The patient was asked if his wife had ever dressed his leg for him and he replied that he always dressed it himself but that his wife collected the soiled dressings and burnt them. There was no other illness in the house nor had anyone living near him, so far as he knew, recently had typhoid fever. He was taken to the clinical laboratory and a bacteriological examination of the sinus was made by Mr. Dudgeon whose report is given below.

Bacteriological report.—At the examination made in July, 1905, of the pus obtained from the sinus typical blue colonies appeared on the medium of Drigalski and Conradi, which had been inoculated with the pus, and from these colonies pure strains of the typhoid bacillus were obtained. The bacillus also gave the cultural characters of the typhoid organism in urotropin broth. The patient's serum failed to agglutinate this bacillus but a complete typhoid reaction was obtained with a standard laboratory strain of positive typhoid serum and the bacillus isolated from the patient's leg, while typhoid horse serum also gave a complete instantaneous reaction with the bacillus in a dilution of 1 in 1000. On Dec. 9th the pus obtained from the right femur was again examined with a similar result.

As the sinus persisted Mr. Battle, on Feb. 16th, 1906, made an incision over the old scar down to the femur. The periosteum was rough and thickened and this was divided. There was a cavity in the interior of the bone which was scraped out, several small pieces of bone being removed. The wound was syringed out with saline solution. A culture taken at the time of operation showed the presence of the typhoid bacillus. Subsequently the wound was irrigated daily with 1 per cent. urotropin¹ and after a few days the discharge was found to contain no typhoid bacilli; at the end of March a second examination was made with a similar result.

Remarks by Mr. DUDGEON and Dr. GRAY.—For some years it has been well recognised that the bone complications of enteric fever are due, in a majority of the cases, directly to the bacillus typhosus, but sufficient stress does not seem to have been laid upon the danger that these cases may be to the community at large. At a London hospital, where the demand upon the beds is necessarily enormous, a number of cases of suppurative bone disease have to be discharged before their wounds have completely healed and have to attend for weeks or even months as out-patients. The importance, therefore, of making a careful bacteriological examination in all cases which may possibly be due to typhoid fever, both at the time of operation and before the patient leaves the hospital, cannot be exaggerated. It should be mentioned that when the patient left the hospital his wounds were completely healed and that the sinus did not develop till some weeks later. His past history is taken from articles published in THE LANCET by Dr. Mackenzie² and Mr. Battle with Mr. Dudgeon.³

¹ One of us (L.S.D.) has recently read a communication before the Pathological Society of London in which it was shown that typhoid bacilli will not grow in 1 per cent. urotropin broth.

² THE LANCET, Sept. 26th, 1903, p. 869.

³ THE LANCET, April 22nd, 1906, p. 1065.

Although, of course, it is impossible to say for certain, yet it seems extremely probable that the wife was infected with the typhoid bacillus by her husband and we believe that only one case of a similar kind has been published (the reference to this we are unable to find). Considering the myriads of typhoid bacilli that his wound must have poured out daily it seems strange that she should have escaped for so long a time. As a rule the specific bacilli die out shortly after surgical interference but references are given by Keen⁴ to cases, similar to the present one, in which typhoid bacilli were present in chronic sinuses of some years' duration.

ANCOATS HOSPITAL, MANCHESTER.

THREE CASES OF PANCREATIC DISEASE.

(Under the care of Dr. A. J. RODOCANACHI.)

FOR the notes of the cases we are indebted to Mr. G. Wright, house surgeon.

CASE 1.—The patient was a woman who had been ailing and had lost much flesh during the preceding three months. She was sent into hospital as a case of perforated gastric ulcer on April 20th, 1904. After admission she vomited a quart of green bilious fluid. There was resistance in the right upper quadrant of the abdomen. A large quantity of putty-like faeces was removed from the rectum. The case was considered to be a not very acute intestinal obstruction and so a laparotomy above the umbilicus was performed on the 22nd. The stomach, which was much dilated, was found to fill three-quarters of the abdominal cavity, while the small and large intestines were collapsed. General matting of the surrounding organs by adhesions obstructed the pylorus. A posterior gastro-enterostomy was therefore performed and the abdomen was closed. The gall-bladder which was seen to be enlarged, was not opened at the operation. The vomiting ceased but two days later the temperature rose to 102° F. and on the 26th the patient died.

Post mortem the gastro-enterostomy was found to be holding perfectly well. There was no peritonitis. There were two stones in the gall-bladder. The pancreas was very hard and the pathologist reported that on microscopic examination it showed chronic interstitial pancreatitis.

CASE 2.—The patient was a man, aged 48 years, who had suffered from attacks of biliary colic for the last ten years. An attack had begun six weeks before admission with severe pain, shivering, and sweating, followed on the next day by jaundice which persisted for a week. With the onset of the jaundice the pain subsided and the patient resumed work. Three weeks later he had a similar attack during which the jaundice persisted until a few days before admission and the pain never left him unless he was under the influence of morphine. He vomited often and freely. The operation was performed on April 18th, 1905, through Mayo Robson's incision. Adhesions round the gall-bladder were separated and on opening it some viscid bile and 322 stones were removed. The ducts were palpated but no stones were felt in them. A tube was fixed into the gall-bladder and the abdominal wound was sutured round it. After the operation the pain was in no way relieved and vomiting of fluid like beef-tea set in. The stomach was washed out and calomel was given, while morphine was injected subcutaneously but only temporary relief was obtained and the patient died from exhaustion on the 24th.

Post mortem there was no peritonitis. Fat necrosis was noticed in the small omentum and on examining the pancreas the head was found to be much enlarged. Cutting into it a large cyst containing broken-down blood clot was opened. It was of about the size of a Jaffa orange and occupied the head of the pancreas. The pancreatic tissue surrounding the cyst was about half an inch thick, very dense and fibrous. No stones were present in any of the bile ducts.

CASE 3.—The patient, a man, aged 45 years, had had several attacks of biliary colic during the preceding two years. The present illness began on June 7th, 1905, with severe pain in the epigastrium which was relieved by morphine but returned each time the effect of the morphine had passed off. He was admitted to hospital on June 14th and there was then general distension of the abdomen, especially in the upper zone. There was an ill-defined mass

⁴ Surgical Complications and Sequels of Typhoid Fever, 1889.

to the right of the middle line and extending downwards half way to the umbilicus; this was resonant on percussion and showed communicated pulsation from the aorta. On the same day the abdomen was opened by a median incision. The omentum was found thickened and rolled up so as to form the above-mentioned swelling. Numerous areas of fat necrosis were present in it. The gastro-hepatic omentum was pierced and the lesser sac opened displaying a small cyst in the head of the pancreas. This was opened and one or two ounces of dark altered blood escaped. The cyst was then packed with gauze and drained. The gall-bladder was then opened and eight small stones were removed. The gall-bladder also was drained and the remainder of the abdominal wound was closed. The operation was followed by much shock, restlessness, and delirium, and the patient died early on the next day.

Post mortem the bile ducts were free from stones. The pancreas was found much infiltrated with blood clot. Microscopically the head of the pancreas showed advanced chronic pancreatitis with much formation of fibrous tissue; the rest was infiltrated with recent blood clot.

Remarks by Dr. RODOCANACHI.—It will be noticed that the first two cases were not recognised as pancreatic disease during life, though the character of the feces in the first and the persistent pain in the second might have given a clue to the correct diagnosis. The third was diagnosed before operation, inasmuch as the mass resonant in front and communicating pulsation from the aorta behind must be in the situation of the pancreas or the small sac of peritoneum. The diagnosis was confirmed at the operation, when the fat necrosis was seen. In all three cases gall-stones were present and might be taken as evidence of the infection of the biliary and pancreatic passages. Death was probably inevitable considering the advanced state of the pancreatic disease, and the best chance of recovery was given by free drainage of the passages through the gall-bladder, together with removal of the gall-stones. Such cases point to the necessity of removing gall-stones and draining the gall-bladder, if possible, before pancreatic infection has occurred.

Medical Societies.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—An extra-metropolitan meeting of this society was held on June 23rd in the medical department of the University of Leeds.—The President, Mr. A. E. Cumberbatch, was in the chair and numerous cases and specimens of interest were shown by the Leeds members, Mr. H. Secker Walker and Mr. A. L. Whitehead. Amongst the former was a young girl, aged 14 years, who had been practically educated as a deaf-mute by lip-reading, &c., after an attack of influenza at an early age. This year she had been put under treatment by inflation and had enormously improved.—In the discussion which followed it was pointed out that many so-called deaf-mutes were amenable to treatment and more careful examinations by skilled otologists were urged upon schools devoted to aural deficiencies.—Among the papers read were *Some Points in the Diagnosis of the Complications of Temporal Bone Disease based upon a study of 135 fatal cases*, by Mr. Whitehead, and *The Influence of Pregnancy and Parturition upon Certain Forms of Progressive Deafness*, by Dr. W. Milligan. In his paper the latter struck an important and valuable note. He pointed out the disastrous effects of child-bearing upon women who were deaf, and especially upon those with a family history of deafness. He questioned whether such people should be allowed to marry.—Mr. P. M. Yearsley, in discussing this paper, drew attention to the fact that it was rather post-parturition conditions, especially lactation, that were to blame and suggested that a careful investigation of such cases by means of blood counts might be of value.—The members of the society were afterwards entertained by Mr. Walker, Mr. Whitehead, and Mr. Michael A. Teale at luncheon at the Queen's Hotel.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—A meeting of this society was held on June 27th, Dr. Alfred Eddowes, Vice-President, being in the chair.—Mr. G. W. Dawson showed: 1. A man with a Peculiar Thickening of the Terminal Phalanx of the Left Thumb which was said to have started as an eczema. The

bone itself was normal as seen by the x rays. 2. A woman, aged 46 years, with Lupus Erythematosus of the Face and Dorsal Surfaces of the Fingers, quite symmetrical in its distribution. 3. A man with Acne Varioliformis of the Scalp.—Dr. Eddowes showed a case of Acute Lupus Erythematosus of the Face in a woman. The lesions themselves were raised and oedematous and there was evidence that the condition was spreading further outward upon the left cheek.—Mr. T. J. P. Hartigan showed: 1. A girl with a Peculiar Eruption around the Nose of 14 years' duration. No member of the society would venture upon a diagnosis of this case. 2. A man with a Vesicular Eruption of the Limbs, symmetrical in its distribution, having some resemblance to a varioloid syphilide. 3. A young man with Darier's Disease and also coloured drawings of this disease taken from this patient and from a girl previously exhibited before the society. 4. An infant with Urticaria Pigmentosa. 5. A young woman with a curious Acneiform Eruption upon the Face and Trunk. From many of the papules small sebaceous plugs had been observed to extrude. The condition was in all probability that of keratosis follicularis contagiosa (Brooke).—Dr. E. G. Graham Little showed: 1. A young woman with Kollonychia or "Spoon-nail." 2. A little girl with a Tuberculide affecting the Lower Limbs, upon which numerous pitted scars could be seen, the results of older lesions. There were no evidences of tuberculosis elsewhere.

Reviews and Notices of Books.

Text-book of Anatomy. Edited by D. J. CUNNINGHAM, F.R.S., Professor of Anatomy, University of Edinburgh. Illustrated with 936 wood engravings from original drawings, mostly printed in colours. Second and revised edition. London and Edinburgh: Young J. Pentland. 1906. Pp. 1388. Price 31s. 6d. net.

THE first edition of Professor Cunningham's text-book met with a very favourable reception and at once made a place for itself among the text-books in common use. Over three years have elapsed since that edition appeared so that those engaged in teaching anatomy have had ample time to find out the merits and the defects of the work. By common consent the most satisfactory sections of the book were admitted to be those devoted to the nervous system, the digestive system, the respiratory system, and embryology. Appropriately enough two of these sections are associated with the name of the editor. In the new edition the list of contributors remains unaltered but the lamented death of Professor A. Birmingham, who as an exponent of visceral anatomy had few equals, rendered it necessary for the editor to revise the section on the digestive system himself. With these preliminary remarks we will proceed to give our impressions of the various sections of the work as it now appears.

First as to embryology, with which the names of Professor A. H. Young and Professor Arthur Thomson are associated. This, which was a very satisfactory feature of the first edition, has been brought up to date and new diagrams in several instances have been inserted. The section on osteology has been greatly improved by the omission of the coloured markings of muscular attachments. We do not say this because we think that these markings subserve no useful purpose; on the contrary, we think that they are of great value to the student but unfortunately in the last edition they were anything but accurate. It is also easy to see how the addition of the coloured outlines detracted from artistic appearance of the drawings of the bones. A new set of the illustrations of the muscular attachments, much more in accord with nature, is found in the section on myology. Reproductions of some radiograms have been added to show the ossific centres of the hand and the foot.

In the former edition the section on arthrology was certainly weak and although it still is rather brief yet we are glad to see that the old illustrations have been largely replaced by a more satisfactory series of drawings on a larger

scale. The adoption of colour printing has improved the appearance of the section on myology. The new illustrations of muscular attachments, which have been prepared by Dr. E. B. Jamieson, we have already referred to. The tables of nerve-supply and of muscular action remain as before. Considering the growing importance of a knowledge of the action of muscles it is a pity that more attention has not been paid to this: the account being tabular is very meagre and might be supplemented considerably. There was but little occasion for alteration in the account of the central nervous system. This was one of the strong points of the first edition, so much so that complaint was made of over-elaboration in this direction. With this criticism we cannot concur and we have many times appreciated the editor's able and lucid exposition of a difficult subject. At the same time we do feel that the introduction of a few simple diagrams showing the continuity of the long motor and sensory tracts and their relative positions at various levels of the cerebro-spinal axis would be of advantage to the student. We notice that new diagrams of the tracts in the posterior columns of the spinal cord appear and the development of the cerebellum is further illustrated. In Fig. 417, which shows the central connexions of the lower cranial nerves, the sixth nerve and its nucleus have been unaccountably omitted. The membranes of the brain hardly receive the attention which their importance merits. Diagrams of the positions and communications of the various spaces might be supplied. The descriptions of the organs of sense and of the vascular system call for little comment but it would materially add to the usefulness of the description of the lymphatics could some diagrams be devised to show the lymphatic areas of the head, the areas and drainage routes of the breasts, and also those of the stomach, the liver, the uterus and annexa, the penis and perineum. Another weak point is the description of the various bursæ. Illustration of these is not difficult and on turning to the index we find that the various sacs are not mentioned by name, so that it is a matter of difficulty to trace them. The section on the digestive system we have already commended.

In various places in the book we find references to the pancreatico-gastric and pancreatico-duodenal folds but can find no formal description of these important structures. In the section on the urogenital system several new and important drawings appear, including new representations of the prostate. The editor and his assistants do not appear to have made up their minds which is the sheath of the prostate and which is its capsule; this is evident on comparing the account in this section with the one given in the section on surgical anatomy.

We have criticised a few points in which we think improvement might be effected. Taken as a whole the book is a trustworthy and lucid guide to the subject of which it treats and may be unhesitatingly recommended both to the beginner and to the advanced student. It will long continue to hold a prominent place amongst English text-books.

Diseases of the Rectum, being a short account of the Symptoms, Diagnosis, and Treatment of some Diseases affecting the Anorectal Region. By F. VICTOR MILWARD, M.B., B.O. Cantab., F.R.C.S. Eng., Surgical Casualty Officer, General Hospital, Birmingham; Surgeon to Out-patients, Children's Hospital, Birmingham. With 27 illustrations, eight of which are original, and have been drawn by the author. Birmingham: Cornish Brothers, Limited, 1906. Pp. 193. Price 5s. net.

FOR its size this is a very complete account of the diseases of the rectum and we do not know any work more suitable for a medical man to read if he wishes to refresh his knowledge of the diseases of this portion of the body. The author is wise in not attempting to

give too much but what he gives is good. The advice as to treatment is judicious. Especially valuable is the chapter devoted to the consideration of the value of operative procedures in rectal carcinoma, for there are few subjects about which more diverse opinions are expressed. Mr. Milward considers that of 100 cases of malignant disease of the rectum from 20 to 25 will be suitable for excision, from 55 to 60 will benefit by immediate colostomy, and of the remaining 20 15 will eventually require it. Thus in about 5 per cent. of cases no operation is advisable. With these figures we agree on the whole. By the bye, we are glad to see that Mr. Milward uses the term colostomy for an artificial anus in the colon. The word colotomy should be reserved for incision of the large intestine.

Gall-stones and their Surgical Treatment. By B. G. A. MOYNIHAN, M.S. Lond., F.R.C.S. Eng. Second edition, revised and enlarged. London and Philadelphia: W. B. Saunders and Co. 1905. Pp. 458. Price 21s. net.

IN the spring of 1904 Mr. Moynihan delivered a course of lectures on gall-stones at the Medical Graduates' College, London, and this book contains the material on which those lectures were based. The first edition appeared in 1904 and was rapidly exhausted so that a new edition has become necessary. There was a very clear need for the publication of a book such as this, for the accounts of gall-stones and the surgery resulting from them given in the ordinary text-books, or even in works specially dealing with the liver, are too brief to be of much practical value. Mr. Moynihan has the happy faculty of writing very readable books and the present volume is no exception to this rule. The use of adequate illustrations is always a great aid to comprehension and the illustrations here are very good. There is naturally in a large book much on which criticism might be based but we will confine ourselves to a few points. Mr. Moynihan, as do most surgeons at the present time, supports "Courvoisier's law," that "in chronic jaundice due to blocking of the common duct a contraction of the gall bladder signifies that the obstruction is due to stone, a dilatation of the gall-bladder that it is due to causes other than stone." We agree that the exceptions to this law are very few but exceptions do occur. In a work of this character we think that it would be well to give the sources for the references and quotations that are made, so that the reader may, if he will, refer to the original book or article. We may also suggest that in a future edition the two indices which are present, one of names of persons and the other of things, should be combined. It is now generally agreed that a single index is more valuable and more easy to use than two or more distinct indices. The book is well printed in a large readable type.

LIBRARY TABLE.

Personal Hygiene, Designed for Undergraduates. By ALFRED A. WOODHULL, A.M., M.D., LL.D. (Princ.), Brigadier-General U.S. Army (retired), &c. London: Chapman and Hall, Limited. New York: John Wiley and Sons. 1906. Pp. 221. Price 4s. 6d. net.—This little book, we learn from the preface, "is intended for undergraduate students and contains the substance of lectures on Personal Hygiene given at Princeton." The first seven chapters are devoted to a brief account of the anatomy and physiology of the human body. This is followed by chapters on the development and care of the body, on physical culture exercises, on fatigue, on elimination of waste and care of the skin, on catching cold, and on clothing. The last three chapters are devoted to the subjects of food, tobacco, and alcohol. On the whole, the first portion of the book is the least satisfactory, as the account given of the structure of the body is too meagre to be of much value, while

in the absence of any illustrations it is doubtful whether a reader unacquainted with anatomy would be much the wiser for a perusal of it. The advice given in the more practical portion of the book is generally sound and useful. On the burning questions of alcohol and tobacco the author is no fanatic. He admits that alcohol is to some extent a food, though not a good form of food under ordinary conditions, and he insists upon its value in many diseased conditions—a truth which is often denied by the teetotal extremists. The harmfulness of tobacco to growing youths is rightly insisted upon. The style of the book is interesting and it is free for the most part from distressing perversions of the English language. A study of it may well be recommended to the undergraduate readers for whom it is intended, if it is possible to persuade young people at that period of life to attend to such a dull and trivial subject as the preservation of health.

Food in Health and Disease. By H. DRINKWATER, M.D. Edin., with a preface by T. R. BRADSHAW, M.D. Dub., F.R.C.P. Lond. The Temple Primers. London: J. M. Dent and Co. Pp. 174. Price 1s. net.—In compiling this primer Dr. Drinkwater is chiefly indebted to the works of Bauer, Cheadle, Chittenden, Hutchison, Roberts, Sir H. Thompson, Williams, and Yeo. In the preface Dr. Bradshaw points out that popular estimation is not a safe guide as to the nutritive value of the various articles submitted to us as food, and, further, that it is necessary to know what modifications are needed in the diet to meet the wants of the human organism at different periods of life, under various conditions of climate and season, and in various states of disease. For those who are studying medicine a scientific and practical knowledge of dietetics is indispensable. Professor Herter of New York, in his admirable lectures on chemical pathology, strongly advises medical students to inform themselves as fully as possible in regard to the chemical and physiological characters of the ordinary articles of food. Still more emphatically he urges them to obtain a practical knowledge of cooking. Dr. Drinkwater has an extensive knowledge of the theory of diet both in health and disease and Dr. Bradshaw writes that he has had good opportunities of testing the correctness of his views in practice. His book should be helpful both to the members of our profession and to the general public. The book treats of the different kinds of food, of cooking, of the digestion and absorption of food, of the force value of food, of food in infancy, during school life, and in old age, of the cost of food, and of food in disease. In an appendix the author gives an epitome of the observations of Professor Chittenden of Yale University on the subject of the necessary amount of albuminous food-stuffs for men under various conditions as to work and exercise, which are set forth in his work entitled "Physiological Economy in Nutrition." A bibliography and an index are included in this little volume.

Outlines of Zoology. By Professor ARTHUR THOMSON, M.A. Fourth edition. London and Edinburgh: Y. J. Pentland, 1906. Pp. 866.—It is interesting to observe that this, the fourth, edition of Professor Thomson's well-known manual is more than 200 pages larger than the first edition published in 1892. The 14 years which have separated the two editions have been so fruitful in zoological discovery that the author's difficulty was not so much in the way of critical revision as in planning how to accommodate insistent new fact. This he has done by being liberal in small type and chary of admitting any but the facts of quite first-rate importance into large type; otherwise a process of budding or fission into two volumes would have been inevitable. This fourth edition contrasts favourably in more than one feature with the work as it was originally printed. The rather coarse plates of the

earlier edition have been replaced by much better illustrations in the text. Some of the latter are new in the sense that they have not yet, so far as we are aware, found their way into any text-book from their native element—the pages of a special memoir. This is the case, for example, with the figure of the brain of *Batteria*, which serves to show how unnecessary an order *Rhynchocephalia* is to include this essentially *lacertilian* reptile. The brain is one of the many features in which *Batteria* betrays its affinities and which forbids its comparison with any other group of reptiles, that is a comparison in which the *lacertilia* generally do not share. The general facts of zoology must be as familiar to Professor Thomson after some years of teaching as they are to others. And we find, therefore, a lack of error in detail which is satisfactory and renders the book trustworthy to the student. Criticism of this manual, indeed, is necessarily confined to minutiae. We object, for instance, to the author's statement when dealing with the anatomy of the *lacertilia* embodied in the phrase "the epigastric or anterior abdominal vein." It is just as well to retain for the large and important vein which joins the portal anteriorly and communicates posteriorly with the pelvic veins the latter of the two appellations offered to us by Professor Thomson and to reserve for a delicate vein which courses along the ventral body wall below this the name of epigastric. Professor Thomson is liable to fall into a kind of inaccuracy so common among writers of text-books as to be characteristic of them—an inaccuracy of implication. He writes, for example: "In some lizards (*chameleons* and *geckos*) the lungs are prolonged into air sacs." This kind of statement, and for the matter of that this actual statement, is to be met with frequently in text-books and is a loose way of stating that in the groups in question the structure mentioned does occur. But it implies something that is not true—i.e., that all the members of the groups are thus characterised. Again, in describing the *prototheria*, the author writes that "the right auriculo-ventricular valve in *ornithorhynchus* is partly muscular as in birds, while in other mammals it is membranous." This statement is true so far as it goes; but as the section deals not only with *ornithorhynchus* but also with *echidna*—for both are *prototheria*—the implication is that *echidna* agrees with "other mammals," which is not the case. However, this mode of statement is not so seriously to be found fault with as sheer error of description; and of this we find nothing in Professor Thomson's useful manual.

Darwinism and the Problems of Life: A Study of Familiar Animal Life. By CONRAD GUENTHER, Ph.D., Professor at the University of Freiburg in Baden. Translated from the third edition by JOSEPH MCCABE. London: A. Owen and Co. 1906. Pp. 436. Price 12s. 6d.—This book will appeal to all educated people who take an interest in scientific questions and who wish to inform themselves as to the actual condition of the theories of life. The greater part of the work is devoted to proving the truth of Darwinism. Every care has been taken to distinguish between facts and probabilities and the deductions which may or may not be drawn from Darwinism are clearly pointed out. The manner in which the book is written is simple because it is intended for the general reader; no knowledge of science is presupposed. The reader is briefly informed on all questions that have a bearing on the theory of evolution: the book gradually educates the reader to grapple with difficult problems—starting from familiar objects it leads on, almost unconsciously, to questions of increasing difficulty, until the reader is at length in a position to form an opinion on even the most complex. The author's scheme is that Nature herself shall teach the reader the truth of evolution; the principles of natural selection are progressively illustrated by facts taken from animal life. As

the translator writes, "The quantity of popular evolutionary literature in our tongue is—apart from works that deal with the subject in its relation to religious controversy—so slight that a fresh work of acknowledged competence should be assured of a welcome. Professor Guenther's work has an especial title to consideration. He has succeeded so well in taking up the position of the average untrained observer for his instructive survey of our animal world that his book will be singularly helpful to thousands who shrink from the usual technical manual." The long introduction is most pleasant and instructive reading and the subsequent chapters pass in review the chief groups of the animal world. Chapter XI. deals with "The Mechanical Conception of Life and its Limits." The author writes: "Natural selection will then modify organisms in the direction of greater simplicity. In our view of the development of the earth there will really be such a time one day. The water on our planet is constantly decreasing, and the time will come when there will not be sufficient left to support human life when the bones of the last man will bleach in the unclouded glare of the sun. But in the last drops that will linger in holes in the vast desert of the earth there will certainly be infusoria. After a time even these creatures will not find water enough; they will perish, and only simpler organisms still will be maintained, until at last all living matter has returned to its mother and changes into lifeless mineral once more." The book will no doubt secure a wide popularity, since it discusses the question with the exactness which science demands and in the light of the most recent research, and at the same time invests the story with something of the charm of a romance; it is not only adapted to the general reader but it also offers the student of evolution a thorough survey of the literature of the subject and is quite up to date. Mr. McCabe's translation is an excellent one, the book is full of charming writing and he is to be congratulated on its appearance. There is a copious index. We think that it would be difficult to find a more suitable and attractive interpretation of evolution, from Weismann's point of view, than is to be found in Professor Guenther's "Darwinism" as given to us by Mr. McCabe.

The Rise and Fall of Reading Abbey. By JAMESON B. HURRY, M.D. Cantab. With illustrations. London: Elliot Stock. 1906. Pp. 119. Price 2s. 6d. net.—This book is a reprint, somewhat amplified, of the author's presidential address to the Reading Literary and Scientific Society last year. Dr. Hurry has also published a larger work entitled "Reading Abbey" which contains fuller details than the present work as well as bibliographical references. In the year 1121 eight black-robed monks left their old home, the splendid and wealthy Benedictine Abbey of Cluny, at the bidding of Henry Beaclerc, to raise a great new monastery to the glory of God. The author tells us about the founding of the abbey, the details of its fabric, and a good deal about its abbots and monks; then he passes on to the storm which overtook the religious houses under Henry VIII. and relates the dramatic martyrdom of the last abbot, and then finally tells the present condition of the ruins. The book contains a chronological list of the abbots and a calendar of the abbey. We congratulate the author on the interesting study of his leisure hours. The book shows a sound knowledge and much careful research. It will no doubt be much appreciated by many lovers of local lore and of antiquarian scholarship. The illustrations are very appropriate and they are well executed.

JOURNALS AND MAGAZINES.

Dublin Journal of Medical Science.—The most important communication in the May number of this journal is that by Dr. J. M. Finny on a case of Bradycardia with Arrhythmia and Epileptiform Seizures. In this instance it was possible

to verify by means of the x rays the independent beating of the auricles between the ventricular pulsations, thus confirming the theory of heart-block as the cause of this condition. The epileptiform attacks coincided with periods of irregularity in the pulse. Dr. T. Gillman Moorhead records a case of Splenic Anæmia in an Infant and Dr. George B. McCaul writes in favour of Intubation in Diphtheria. An appreciation of Franz Joseph Gall, the founder of our knowledge of cerebral localisation, written by Dr. John Knott, tends to redeem the memory of a great scientific observer from the stain of charlatanry with which it has been unjustly smirched and suggests that the speech centre should be associated with Gall rather than with Broca.

Birmingham Medical Review (May).—Dr. Smallwood Savage contributes an interesting study of Hematoma of the Ovary, classifying the varieties of this condition as hæmatomas of the Graafian follicle and of the corpus luteum respectively. Dr. James Miller discusses the Etiology of Coryza, or the common "cold," and tends to regard the staphylococcus pyogenes albus as the causal agent, chill in the form of a draught of cold air causing temporary constriction of the vessels of the nasal mucosa and thus giving the bacteria a chance to invade the tissues.

Ophthalmology. Edited by H. VON WÜRDEMANN, M.D. Vol. II., No. 3. Editorial and publishing office: Milwaukee, Wisconsin, U.S.A. Price per number, 6s.; per year, £1 1s.—This number of *Ophthalmology* contains a good portrait of Swan M. Burnett, M.D., a well-known American ophthalmologist who died at his home in Washington on Jan. 18th, 1906, at the age of 58 years. His attention was particularly directed to the subject of refraction and he wrote a valuable work on astigmatism and contributed many articles to American journals. Amongst the original articles in this number of the journal are: 1. The Relation of Convergence to Accommodation, by Howard F. Hansell, M.D., of Philadelphia. 2. A case of Atypical Exophthalmic Goitre from Endothelioma of the Pituitary and Thyroid Bodies; Death from General Sepsis; Autopsy, with 13 illustrations in the text, by H. von Würdemann, M.D., of Milwaukee, and Wilhelm Becker, M.D., of Milwaukee. 3. Report of a case of Cystic Degeneration of the Pituitary Body, with Pressure on the Optic Chiasm, by W. H. Peck, M.D., of Chicago. 4. Traumatic Iridocyclitis, with peculiar Conjunctival Disease; Recovery under Injections of Tuberculin, by S. D. Risley, A.M., M.D., of Philadelphia. 5. A second case of Keratitis Disciformis, with report of a case of Corneal Erosion, by W. Campbell Posey, M.D., of Philadelphia. 6. A case of Filamentous Keratitis, illustrated, by William Zentmayer, M.D., of Philadelphia, and H. C. Goldberg, M.D., of Philadelphia. 7. Dangers of Common Drugs, as seen by an Ophthalmologist, by Edmund E. Blaauw, M.D., of Buffalo. There are, in addition, numerous abstracts of current literature and reviews of books.

New Inventions.

A NEW CRUTCH BED-REST.

THE ordinary form of bed-rest has the disadvantage of allowing the patient to slip from the position in which he or she has been placed, however carefully propped up by the nurse with pillows. In the Claxton crutch bed-rest, the object of which is to prevent the patient from slipping after being placed in position, a semicircular padded crutch is placed under each arm of the patient and screwed to the sides of the bed-rest. By means of adjustable screws the crutches can be easily raised or lowered to any height required and also to the width of the patient's back. The price per pair of the crutches is £2 2s. and they can be obtained of the inventor, A. Claxton, 62, Strand, London, W.C.

THE LANCET.

LONDON: SATURDAY, JULY 7, 1906.

The Metropolitan Hospital Sunday Fund.

SOME little time has passed since the day selected for the annual collection on behalf of the Metropolitan Hospital Sunday Fund and the returns which have been made will have enabled individual congregations to congratulate themselves upon such increase as may be observable in the offerings to which they have contributed, or to deplore, in some instances, a falling off. In the majority of cases the figures will be found to be not very different from those of last year, particularly in those not affected by the vagaries of fashion, such as the increasing popularity of excursions out of London at the close of the week. It will also be borne in mind when differences occur that in congregations where the annual sum may be expected to amount to something less than £50 the presence or the absence of a single donor whose anonymous generosity is conveyed in bank notes is likely to make itself felt in a marked degree. We again express the hope to which we have given utterance before, that those who for any reason have not been present to be reminded by the words of the preacher or by our supplement lying before them will not have allowed themselves to forget the needs of the suffering poor and that others will have remembered that the poor treated in the hospitals to which the Fund grants aid are not drawn from areas limited according to the situation of the individual institution, but that they come from all parts of this vast metropolis, from its ever-increasing suburbs, and in many instances from distant parts of the country. It is to the poor of all nationalities and of all creeds that the hospitals hold out helping hands and to whom, in the words of Prebendary M'CORMICK quoted in our supplement, "they save untold pain, they remedy distressing defects, they give hope and life when despair sets in and death threatens," and it is to an equally widely distributed almsgiving public that the metropolitan hospitals look for pecuniary assistance. The document referred to, the supplement published annually by THE LANCET in aid of the Metropolitan Hospital Sunday Fund, contained this year extracts from letters written by clergymen and ministers whose congregations contribute annually. Only small portions could be inserted owing to the limited space at our command but the response made to the request for opinions upon the work done by our hospitals and kindred institutions was of considerable interest, the most prominent points to be observed with regard to it being the varieties of religious belief represented by the writers and their unanimity with regard to the topic upon which they wrote.

In the ordinary course of events within 12 months time we shall again be addressing our readers, or

rather a circle of readers extending far outside the limits of the profession of medicine, and shall be urging upon them the necessity not only of maintaining their subscriptions to the Metropolitan Hospital Sunday Fund at their usual high level but of increasing them so that in a proportionate degree the beneficence of the hospitals may be augmented and extended. If they are indifferent in the matter or if they are insufficiently informed as to what that beneficence is we would now suggest that during the coming year they should take steps to secure fuller information on the subject. Hospitals are busy places where the good work must necessarily be done without spectators for the most part, but nevertheless there are occasions when hospitals may be visited without interfering with their routine and none need miss the opportunity, should they seek it seriously, of ascertaining from some humble member of the poorer classes what the hospital has done for him or her. The hospitals have nothing to lose by investigation and inquiry. On the contrary, the wider the knowledge is extended of what is achieved within their walls the wider and the deeper will be the sympathy with their aims and with the difficulties under which those aims are pursued. These difficulties are mainly financial and they arise from causes which are wholly beyond the control of any hospital committee and which show no sign of diminution or of becoming less active in their operation. We will refer once more briefly to those causes because we have suggested that again next year we shall plead on behalf of the hospitals and because we shall of necessity be compelled to refer to their need as one which is increasing and which is not likely to be diminished. Not many days ago London was startled and many were no doubt alarmed by a very serious accident accompanied by death or injury to many persons and caused by an electric tramcar becoming unmanageable upon a steep gradient. No doubt those who read accounts of the accident in the newspapers reflected that the wounded were conveyed to hospitals in the immediate neighbourhood of the disaster and they, perhaps, thought for a moment how useful hospitals may be in such emergencies. Few, however, we believe, will have considered the work of the hospitals in such a case as this, looking upon it in the light of all the circumstances which tend to increase the strain upon the hospitals' resources. We would therefore point out that this was an occurrence due to an application of electricity which, at a very moderate distance of time, say 40 years ago, had no existence, that there was a collision with a motor omnibus, a vehicle which far more recently would have been regarded as a would-be inventor's dream; and that these vehicles were running through busy and crowded streets where 40 years ago country carts went their peaceful way along what were practically country roads, going under Highgate Arch, a structure now wholly passed away and replaced by an example of more modern engineering. All around the spot where the accident took place stand thousands of buildings, many of them inhabited by the poorer classes, occupying what were green fields 40 years ago, and the thoroughfares lead into other like districts, many of them equally populous but still more recently occupied. We have here examples of modern scientific progress in the methods of locomotion having as their equivalents in the hospital

all the costly apparatus and equipment, all the improvements of building and sanitation, which necessitate annually a fresh and an increasing expenditure. We have also an instance of the expansion of London and of the increase of the population which seeks to earn its scanty living in and around the great metropolis and which, when disabled by illness or injury, must depend upon the hospital for treatment. We have, moreover, a reminder that the inventions of science, the increase of commercial enterprise, and the multiplication of objects upon which the energy of workers may be expended do not make human life safer or more free from sudden and unexpected danger than it was in the more tranquil times when our older hospitals were founded by wise and benevolent citizens. We have, in short, a combination of examples of the changes which time brings and with which the hospitals must struggle to keep pace if they would maintain their proud position in our social economy. The London of 40 years ago which those who do not yet reckon themselves elderly can well remember was widely different from the London of to-day and the progress which has taken place has been so rapid that any corresponding increase in the fixed resources of the hospitals has been impossible, so that they have to face the growing demand for their aid by asking for more liberal contributions from the benevolent public from year to year. We may, therefore, without anticipating what may be the condition of London 40 years hence, predict with confidence that next year we shall appeal on behalf of the Metropolitan Hospital Sunday Fund with no less cause for doing so than we have had in the past. In return for that which has been given in 1906 and in preceding years there will ever be the record of splendid work done and the unrecorded but, let us believe, deep and sincere gratitude of those saved from sickness and pain incalculable.

Insanity and Senile Dementia.

DR. DAVID NICOLSON, in his letter published in THE LANCET of June 9th, p. 1635, drew useful attention to the marked decline in the proportion of pauper patients discharged from lunatic asylums compared with the proportion of discharges among private patients and also to the effect of this decline as affording some explanation of the alleged increase of insanity. In order, however, to provide a satisfactory solution of the problem whether the alleged increasing prevalence of insanity is a reality it is necessary more closely to define the signification of the term insanity and also to differentiate the various forms of mental unsoundness. In the interests of the public it may be necessary equally to certify as insane those suffering from congenital idiocy, from acute mania, from general paralysis, and from senile dementia. If, however, there be reasonable ground to demand more scientific treatment of insanity as a microbic disease, the question arises whether these varying forms of mental unsoundness can be treated as mere variations of the same disease. Moreover, even should this question be answered in the affirmative it would be necessary, in view of this problem of the alleged increase of insanity, to ascertain the relative increase of the certified insane suffering from the several forms of unsoundness.

The Commissioners in Lunacy in their last issued annual report called attention to the growing tendency to send aged persons, most of them presumably suffering from senile dementia, into asylums. It is pointed out that during the five years 1884-88 the annual number of persons aged upwards of 65 years admitted to the asylums in England and Wales was equal to 99 per 100,000 of the population living at those ages; whereas 15 years later (in 1899-1903) the annual proportion of such admissions had increased to 143 per 100,000. This shows an increase during these 15 years of 44 per cent. in the mean annual rate of admissions to the asylums of persons aged upwards of 65 years; or, stated in another way, that while the annual number of such admissions averaged 1267 in the five years 1884-88 it had increased to 2145 in 1899-1903, an annual increase of 878 admissions at these advanced ages. This marked increase in the admissions to the asylums at these ages naturally includes such cases, whether transferred directly from home or from workhouses. The last report of the Commissioners in Lunacy contains, however, much interesting information concerning 1455 cases of admissions of persons aged upwards of 70 years to 83 asylums in England and Wales during the years 1903 and 1904 directly from 393 union workhouses. Of these 1455 cases, 690 were transferred from workhouses to asylums in 1903 and 765 in 1904. It is further noted that 1141 of these admissions were of persons aged between 70 and 80 years of age and 314 of persons aged upwards of 80 years, including 18 who exceeded 90 years of age. The Commissioners discuss in their report the desirability of this growing tendency to transfer these senile cases from workhouse to asylum and while admitting that in many cases the transference is justifiable, if not necessary, they express the opinion that in many instances it has been effected without due discrimination and has operated prejudicially on the patient.

Special attention is called to the very considerable proportion of these aged transferred patients who die within a short period of their transfer to the asylums. It is certainly somewhat startling to learn that of the 1455 senile cases transferred from union workhouses to asylums in 1903 and 1904, 37, or 2·5 per cent., died within a week; 175, or 12·0 per cent., within one month; 502, or 34·5 per cent., within six months; and 666, or 45·7 per cent., within one year of their transfer. These are the mean percentages of deaths among the 1455 admissions at these ages directly from the union workhouses to the 83 asylums in England and Wales during the two years. The proportional fatality varied, however, very widely among the admissions from different localities. For instance, the deaths among the 310 admissions at these ages from the metropolitan workhouses to the London asylums within a year of the transfer did not exceed 27·7 per cent., whereas among the 239 admissions to the Essex and West Ham asylums from the Essex workhouses the deaths during the first year were equal to no less than 56·4 per cent. As the result of inquiries on this subject addressed to the asylum authorities a large proportion of the medical superintendents expressed the opinion that these transferred senile cases were unsuitable for workhouse treatment, as no proper accommodation or supervision is provided in the workhouses from which the patients were transferred. The medical superintendent of Colney Hatch

Asylum, however, expressed the opinion that 32 out of the 49 cases transferred to that institution might have been treated in a special ward of the workhouse infirmary, but that it was doubtful whether any would have been suitably cared for in an ordinary infirmary ward. The Commissioners limited this inquiry to the pauper insane transferred from workhouses and did not deal with those cases of persons admitted directly from their homes at the same advanced ages, who number, as they state, approximately twice as many as the former. It thus appears that during the two years 1903-04 nearly 3000 persons aged upwards of 70 years were admitted to the English asylums and were thus added to the number of the insane under the care and control of the Commissioners in Lunacy.

Apart from the important question as to the expediency of the transference of these cases of senile dementia, which arises from the inquiry of the Commissioners in Lunacy, the facts referred to above suggest a reasonable doubt whether the recent marked increase in the proportion of such cases admitted to the English asylums does not go a long way to explain the alleged increase of insanity. It at any rate accentuates the desirability of a more careful and scientific differentiation of the various forms of insanity and suggests an inquiry whether all these cases of senile dementia are correctly classed with the insane. In the meantime it would be interesting to know whether the 1455 senile cases of transfer from union workhouses to asylums during 1903-04 had previously to the transfer been classed as insane inmates of the workhouses, or whether any considerable proportion of the cases were specially certified as insane to enable the transfer to be made.

The Archives of the University of Manchester.

THE University of Manchester has taken the important and highly commendable step of commencing the publication of the archives of its public health laboratory and has issued, under the able and judicious editorship of Professor SHERIDAN DELÉPINE, the first volume of a series that promises to be of no small interest and value alike to members of the medical profession and to those of the laity who can be led to take an intelligent interest in the conditions by which public health may be endangered or in the precautions by which it may be preserved. The editor explains that as a teaching department of the University the public health laboratory is concerned in the exposition of knowledge by means of lectures and demonstrations and that well-known hygienists have been invited from time to time to deliver lectures upon subjects which they have made their own. The present volume is devoted to the publication of lectures delivered during the year 1904 and of a few reports which formed the bases of demonstrations given by members of the laboratory staff in connexion with these lectures. Original communications bearing upon diseases which are prevalent in the districts surrounding Manchester, or dealing with food- and water-supplies, air, disposal of refuse, sterilisation and disinfection and kindred subjects, will be published in future

volumes; and it is manifest that these, as they successively appear, will form a constantly increasing body of trustworthy information upon subjects which are not only of the highest interest to the profession but of supreme importance to the public. It is much to be hoped that the authors of future communications and the editor will alike keep this double relation of their subject-matter constantly in mind, in order that the projected series may come to be recognised as an authoritative exposition of the nature and aims of sanitary work of the highest class, and that it may assist the public to recognise the character of such work and to distinguish it from the foolish claptrap which, in non-professional journals, is not infrequently made to do duty in its stead. Antivaccinationists, "Christian scientists," and similar morbid outgrowths of popular ignorance and conceit owe their very existence to the absence of any general diffusion of knowledge concerning the aims and tendencies of medicine, and such knowledge may be more easily imparted on subjects connected with the prevention of disease than on those connected with its treatment. Professor DELÉPINE and his fellow-labourers will act wisely if they bear in mind the advantages which would accrue from the formation of fresh links of intelligence between the public and the medical profession, and from a better understanding than now exists, on the part of the former, of the extent to which the principles of medicine are becoming based upon strictly scientific analyses of facts and are taking the position of certainties capable of demonstration which it is no longer possible for any but the ignorant to dispute. If we might venture upon a suggestion to an editor of Professor DELÉPINE'S knowledge and sagacity it would have reference to the expediency of exerting a strict control over the tendencies of future contributors to be unnecessarily technical or to express in *quasi*-Greek, which would be double Dutch to an Athenian, occurrences admitting of interesting and lucid statement in English.

Among the most interesting of the communications in the present volume is one by Dr. ARTHUR NEWSHOLME, medical officer of health of Brighton, on the Rôle of "Mixed Cases" in the Spread of Infectious Disease. It is a commentary upon numerous instances in which preventive measures against infection have been rendered partially futile by failures of diagnosis; and the difficulties hence arising, which are encountered in the course of almost every epidemic and which have been deplored by almost every observer by whom an epidemic has been investigated, are illustrated by well selected examples. Dr. NEWSHOLME dwells also upon the occasional communication of disease by persons in whom the infective stage is erroneously supposed to have passed away, and in this connexion he gives a salutary warning concerning the limits of utility of bacteriological investigation. There is no doubt that undue reliance has often been placed upon the merely negative sign afforded by the absence of the bacillus of diphtheria from the mucus removed from the throat on some single occasion, and Dr. NEWSHOLME is accustomed to attach a notice to every certificate issued from his laboratory after the examination of a "swab," a notice reminding the sender thereof that the absence of the bacillus does not imply that the case is not diphtheria and that this must be decided on clinical grounds

or on the examination of further specimens. He speaks of instances in which the failure of one endeavour to find the bacillus has induced a medical man to say that there was no diphtheria and improperly to release the patient from isolation, and he further points out that the bacteriological test, if employed to relieve practitioners from the onus of diagnosis in fairly characteristic clinical cases of diphtheria, may be harmful by leading to delay in treatment by antitoxic serum and may even, if the bacillus be missed and a negative result obtained, lead to a dangerous withholding of specific treatment. In very weighty words he lays down the proposition that the true scope of bacteriological diagnosis is for atypical cases which might otherwise be overlooked and that we cannot afford to displace clinical diagnosis from its first and most important position. The warning is of equal value in relation to many other classes of investigations and of disease, for an undue reliance upon methods and instruments of so-called precision has too often been conducive not only to neglect of clinical observation but also to an erroneous belief that such neglect can be made good by methods of a more or less mechanical character, methods often excellent as helps to the really trained observer but never really effective as substitutes for educated touch, educated hearing, and educated sight.

A highly instructive paper by Mr. FRANCIS VACHER, medical officer of health of Cheshire, is illustrated by numerous figures displaying methods by which fraudulent or unskilful plumbers and other workmen have succeeded in neutralising the intended effects of sanitary fittings and appliances of various kinds, and in distributing sewer gases and other abominations through sleeping and dwelling rooms; and the drawings are especially interesting inasmuch as they are all representative of actual conditions encountered by the author in the course of his professional avocations. Dr. J. C. THRESH, the medical officer of health of Essex, discourses learnedly on water filtration in connexion with public supplies, and explains the various conditions under which one or another method of purification must be preferred, the effect of his observations being to show that there is no general rule in the matter, and that every locality must be dealt with in the manner rendered necessary by the actual conditions which it presents and which must be investigated and understood before any system can be recommended for adoption. The object may be merely to remove suspended mineral matter, or it may be to remove low forms of vegetable life other than bacteria, or it may be to remove bacteria of a dangerous or objectionable character, or to remove organic matter held in solution. These several conditions will be determined mainly by the character of the collecting ground, and the degree in which they are present, either singly or in combination, must determine the treatment necessary in the particular case. There is therefore no legitimate opening for the ignorant application of any so-called "rule" by unskilled persons; but there must in the first instance be a study of facts conducted with scientific accuracy, followed by an application of principles to the conditions which are thus disclosed. An essay on Feeding in Relation to the Health of the Young, by Dr. JAMES NIVEN, medical officer of health of Manchester, deals in masterly

fashion with a problem which is engaging the attention of many classes of the community and upon the correct solution of which it is possible that much of our future national prosperity may depend. Dr. NIVEN lucidly explains the general subject of food values, with especial reference to the cost of provisions of different kinds, and adds his voice to the voices of many who have preceded him in urging the constantly increasing necessity of educating girls of the industrial classes in subjects which are of such vital interest to them as cookery and the proper selection of food materials for families. The utter practical worthlessness of most of what is called elementary education is a tempting topic but it is one to which the eyes of the public are, we believe, gradually being attracted and upon which, at all events, we must not dwell for the present. We have only space in which to call attention to the account of an inquiry, conducted by Professor DELÉPINE himself, into the existence of an alleged nuisance arising from certain tanneries at Grappenhall, to which an outbreak of diphtheria in the neighbourhood had been erroneously attributed. It would be difficult to find an example of a more careful ascertainment of facts or of more conclusive reasoning upon them when they were ascertained. The investigation may be taken as an almost perfect model of a complicated and difficult inquiry, so conducted as to lead to unassailable conclusions.

Annotations.

"Ne quid nimis."

THE BIRTHDAY HONOURS.

THE Birthday Honours list includes the names of several members of the medical profession—namely, Dr. Robert Farquharson, Sir Christopher J. Nixon, Professor A. R. Simpson, Professor A. E. Wright, Deputy Surgeon-General John McNeale Donnelly, C.B., I.M.S. (retired), Surgeon-General Alfred H. Keogh, C.B., Director-General of the Army Medical Service, Surgeon-General William Simson Pratt, A.M.S., Colonel Henry Kellock McKay, C.I.E., I.M.S., and Lieutenant-Colonel David Prain, I.M.S. Dr. Farquharson, who becomes a Privy Councillor, was for many years M.P. for West Aberdeenshire, and was formerly an assistant surgeon in the Coldstream Guards and medical officer to Rugby School. He has held among other offices that of physician to the Belgrave Hospital for Children and of assistant physician at St. Mary's Hospital, where he was also lecturer on materia medica. He is the author of several works on medical subjects and as a Member of Parliament has conscientiously represented his profession. Sir Christopher Nixon, upon whom has been conferred a baronetcy, is the representative of the Royal University of Ireland on the General Medical Council, and has held the office of President both of the Royal College of Physicians of Ireland and of the Royal Veterinary College in that country. He is senior physician to the Mater Misericordiae Hospital, a member of the Senate of the Royal University, and professor of the practice of medicine in the Catholic University. He, too, is the author of several contributions to the literature of medicine. Professor Simpson and Professor Wright have received the honour of knighthood. Professor Simpson, emeritus professor of midwifery and diseases of women and children at the University of Edinburgh, was at one time dean of the Faculty of Medicine at that University. He is a honorary Fellow of the American Gynaecological

Society and of the Obstetrical Societies of Berlin, Italy, Leipzig, Moscow, and Paris. In addition to being editor of Sir James Simpson's "Clinical Lectures on Diseases of Women" he is the author of several contributions to the literature of obstetrics and gynaecology. Professor Wright, who is now attached to St. Mary's Hospital, was from 1892 to 1902 professor of pathology at the Royal Army Medical School, Netley. He was a member of the Indian Plague Commission from 1898 to 1900. His brilliant pathological work in connexion with antityphoid inoculation and the discovery of the oregonins is well known to all readers of THE LANCET and has recently obtained for him the Fellowship of the Royal Society. Deputy Surgeon-General Donnelly and Surgeon-General Keogh, Director-General of the Army Medical Service, have been promoted to be Knights Commanders of the Order of the Bath. Surgeon-General Pratt, principal medical officer of the Southern Command, is made a Companion of the Bath, as is also Colonel McKay. Lieutenant-Colonel PRAIN, director of the Botanical Survey of India, superintendent of the Royal Botanical Gardens, and Government Quinologist, Calcutta, receives a Companionship of the Order of the Indian Empire. To these gentlemen, in the name of the medical profession, we offer hearty congratulations. Mr. J. L. Langman, Mr. Edgar Speyer, and Mr. Felix Schuster, upon whom baronetcies have been conferred, have shown practical sympathy with the work of healing and our readers will be glad to see their names in the Honours list. Sir J. L. Langman organised and sent to South Africa and maintained throughout the late war a fully-equipped field hospital. Sir Felix Schuster is treasurer of the Great Northern Central Hospital and Sir Edgar Speyer has been a munificent supporter of hospitals and has done much to encourage improved systems of hospital administration. And it may be noted that a knighthood has been given to Mr. Luke Fildes, R.A., whose picture of "The Doctor" has been so appreciated by the public. Finally, we must offer our congratulations to the Lord Mayor of London upon the occasion of his being created a baronet. Sir Walter Vaughan Morgan has rivalled the most energetic of his predecessors in the endeavours to promote the success of the Metropolitan Hospital Sunday Fund during his year of office. He has, moreover, long taken an active and practical interest in the welfare of our great medical charities.

THE DERAILMENT OF RAILWAY TRAINS.

THE appalling disaster on the London and South-Western Railway at Salisbury directs attention again, in unhappily a very forcible way, to a question which we have more than once raised in our columns¹ as to whether the practical working of our railways is efficiently supervised. During the last few years we have had several instances of railway accidents due to derailment, and curiously enough there was a case of derailment on the Great Eastern Railway within a few hours of the Salisbury disaster. We need not point out that every linear foot along miles and miles of a railway may become a source of danger, perhaps by reason of subsidence, by a crack in the steel, by the loosening of a "chair" or pin, or by expansion or contraction through sudden changes in the weather. The utmost and frequent supervision of the track is therefore called for. The suggestion may be wrong but it is interesting to observe that recently parts of the country have been subjected to shocks of the nature of an earthquake and these shocks have been followed by more than one instance of derailment. The displacement of earth might, of course, easily account for such accidents, but there are many other happenings which would lead to derailment—as, for

example, the travelling of the train at too great a speed round a curve, the snapping of an axle, or the coupling-up of carriages of irregular size and weight. There is a great craze nowadays for speed in travelling and severe competition encourages our railway companies to comply with this demand but a great speed should not be attained at the risk of safety. We may be confident that the Board of Trade will make the most searching explication in regard to this recent disaster, though it must be difficult to obtain trustworthy facts in view of the completeness of the wreckage of the train and of the damage caused to the permanent way by the derailment. We do not forget, however, that on more than one occasion of derailment the Board of Trade has reported that the supervision of railway tracks and rolling stock is not conducted with that precision and frequency which in the interest of the safety of passengers are desirable, a view which we were led to express on the occasion of the somewhat sudden and casual discovery on the South-Eastern line that one of their tunnels threatened to collapse.

THE IMPORTANCE OF BONE LESIONS AFTER TYPHOID FEVER.

THAT bone lesions, both periosteal and medullary, occur not uncommonly as sequelæ of typhoid fever is very generally known. In cases which go on to suppuration the fact that the discharges containing active typhoid bacilli may be the means of spreading the disease has been very generally overlooked. The bacilli of typhoid fever were traced to the medulla of bones by Chantemesse in inoculation experiments in animals, while in the human subject definite changes in the bone marrow have been described. It is not therefore surprising that the osseous lesions develop. Statistics show that they are commoner in the bones of the lower limbs and that in many cases the abscesses which form yield a pure culture of typhoid bacilli. In a few cases a long interval has elapsed between the disease and the development of the bone lesions. In a case recorded by Buschke there was an interval of 46 years and yet active typhoid bacilli were found in the pus from the bone. A case of this kind recorded in this week's issue, p. 26, by Mr. L. S. Dudgeon and Dr. Ronald E. G. Gray illustrates the possible danger of such cases in spreading the disease. The patient was treated at St. Thomas's Hospital in 1902 for a severe attack of typhoid fever, in the course of which a perforation of the ileum was successfully sutured by Mr. W. H. Battle. Shortly after the patient's discharge from the hospital in September of that year he was readmitted for pain in the right femur and knee which subsided under local treatment and the administration of iodide of potassium. In October, 1904—i.e., after a lapse of more than two years—he returned to the hospital with an abscess of the lower third of the right femur, from the pus of which Mr. Dudgeon isolated the bacillus typhosus in pure culture. The patient left the hospital with the wound soundly healed in December, 1904, but shortly afterwards a sinus formed and continued to discharge. In June, 1905, he returned to the hospital and was treated for this sinus as an out-patient. Shortly afterwards his wife was admitted suffering from a severe attack of typhoid fever from which she eventually died. At this time typhoid bacilli were still to be found in the discharge from the wound. On questioning the patient it was discovered that he had dressed the wound himself but that his wife had collected the soiled dressings and burnt them. It therefore seems probable, in the absence of any other known source of infection, that the patient's wife was infected by the bacilli in these dressings. Mr. Dudgeon and Dr. Gray draw attention to the importance of making a bacteriological examination in all cases of bone disease which may possibly be due to typhoid fever in order to avoid the spread of the

¹ Vide THE LANCET, Sept. 6th (p. 686) and Oct. 11th (p. 1002), 1902.

infection by this means. Their case emphasises the importance of dealing with all the discharges from patients suffering from typhoid fever. It is not so very long ago that the importance of the urine as a means of infecting other persons was recognised and there is little doubt that neglect in dealing with the urine has been responsible for the spread of the disease in the past. The long time which the bacilli may continue to be found in the discharges from a sinus connected with a bone lesion, though exceptional, as pointed out by Mr. Dudgeon and Dr. Gray, is yet not to be lost sight of. A further point of interest in connexion with this case was the beneficial effect of irrigation with a 1 per cent. solution of urotropin, in which typhoid bacilli will not grow, since after a few days no typhoid bacilli could be found in the discharges.

SUBURBAN DEATH-RATES.

THE value of the death-rate as the barometer of public health and as a stimulating influence on health progress can scarcely be overrated. The value and increased use of the death-rate in recent years render it, however, the more necessary that its limitations should always be borne in mind and duly appreciated. The Registrar-General's reports have long warned the public that the crude death-rate of a population, without correction for age and sex constitution, may frequently induce false inferences. There are, moreover, other disturbing influences, more especially in the case of suburban death-rates, allowance for which is fully as necessary, but not so simple, as correction for age and sex distribution. In his last annual summary for 1905 the Registrar General publishes in a table side by side the crude death-rates during that year in 76 of the largest English towns, and the corrected death-rates, after due allowance for the age and sex distribution, of the population of each town. The age constitution of nearly all town populations is conducive to a low rate of mortality and consequently the corrected death-rate is higher than the crude rate; in watering places, however, such as Brighton, Hastings, Great Yarmouth, and so on, the undue proportion of elderly persons raises the recorded death-rate, and the corrected rate is in such cases lower than the crude rate. The corrected death-rate in these 76 towns ranged last year from 8.63 per 1000 in Hornsey to 23.44 in Merthyr Tydfil but it can scarcely be held that these corrected rates imply the true relative health condition of these two towns. Hornsey is obviously a suburban portion of the metropolis, although not forming part of the County of London, and it is a fact that in this list of 76 towns, ranged in order of their corrected rates of mortality from the lowest, four other suburban towns (King's Norton, Leyton, Handsworth (Staffs), and Walthamstow) follow Hornsey with the lowest rates. Now there can be no question about the extremely satisfactory health condition of Hornsey; and it is a fact that the deaths of infants under one year of age in this district did not exceed 66 per 1000 registered births—a considerably lower rate of infant mortality than prevailed in any other of the 76 towns. The birth-rate in Hornsey last year, however, was so low as 18.5 per 1000, which sufficiently proves the abnormal constitution of the population in this suburban district. Moreover, an annual death-rate of 8.63 per 1000 in a stationary population would imply a mean duration of life of about 116 years, which forbids the acceptance of the rate as a true indication of the rate of mortality of the 84,070 persons estimated to be living in the district in the middle of last year. It appears from the last census report that of the 40,791 females of all ages residing in Hornsey in 1901 6816, or 16.7 per cent., were domestic servants and that the proportion of domestic servants was equal to 43.8 per cent. of the separate occupiers, the mean proportion in the County of

London being 23.0 per cent. This large proportion of domestic servants not only indicates that the population includes an exceptional number of the well-to-do and servant-keeping class but it also unduly depresses both the birth-rate and death-rate, as domestic servants are as a rule unmarried or widowed and when ill generally leave the district in which they are in service. Moreover, such suburban districts as Hornsey very seldom contain either work-house or hospital, and it should be borne in mind that 37.5 per cent. of the deaths debited to London by the Registrar-General in his Annual Summary for 1905 were recorded in workhouses, hospitals, and lunatic asylums, against 35.0 per cent. in 1904. These remarks (except as regards deaths in institutions) apply with almost equal force to the death-rate in the metropolitan borough of Hampstead which, although included within the County of London, is distinctly suburban in character. The recorded crude death-rate last year among the 88,142 estimated residents within this borough did not exceed 9.3 per 1000 and after correction for the age and sex constitution of the population it is only raised to 10.5, scarcely more than half the corrected rate in the metropolitan borough of Shoreditch, which was 20.6. It is a fact, however, that no less than 27.0 per cent. of the enumerated female population of Hampstead in 1901 were domestic servants, who averaged 79.8 per cent. of the separate occupiers; whereas in Shoreditch only 2.4 per cent. of the females were domestic servants and their proportion to separate occupiers did not exceed 5.5 per cent. These facts and considerations seem to suggest that death-rates for suburban districts, even if corrected for sex and age constitution, should not be accepted as altogether trustworthy indications of the relative health condition of their populations without due allowance for other disturbing factors.

BIER'S TREATMENT OF INFLAMMATION BY PASSIVE CONGESTION.

FOR some years Professor Bier has advocated a rather revolutionary method of treating acute inflammation—the induction of passive congestion—and has reported remarkable results. His method is now being extensively employed on the continent, as the large number of papers advocating it show. There is ample evidence that it gives results attainable in no other way. In this country as yet it has had little vogue. In the *Scottish Medical Journal* for April Mr. C. W. Cathcart has reported a number of cases treated at the Royal Infirmary, Edinburgh, in which its value is confirmed. To these we have previously referred.¹ Professor Bier, in opposition to the old antiphlogistic idea, regards inflammation as a curative process which ought to be encouraged and utilised. In a case of acute whitlow extending along a tendon sheath to the wrist he binds a piece of Martin's rubber bandage around the upper arm. In inflammation affecting the foot he applies the bandage to the thigh—i.e., always some distance above the seat of disease. The bandage is put on sufficiently tight to obstruct the venous return but to diminish only slightly the arterial flow. In acute cases the pressure is very light. Any accessible pulse below the bandage should be easily felt and the limb should be warm. A test of the proper degree of tightness is the relief of pain. Sometimes much patience is required before this degree is attained. When it is the rapid relief is striking. In a few cases, chiefly gonorrhoeal, pain may be at first increased, although it afterwards diminishes. Another test of the proper application of the bandage is the effect upon the whole limb, which begins to swell while the fiery red colour of the inflamed part extends up to the bandage. When the oedema is well established serum escapes freely from any wound which may exist. In bad cases the passive congestion is kept up for 22

¹ THE LANCET, Feb. 17th, p. 451.

out of the 24 hours and this period may be diminished by degrees to ten or eight hours. The position of the bandage should be changed after remaining about ten hours in one place. In the intervals of relaxation the limb should be raised so as to favour absorption. Any pus which may form should be let out but the incision need not be so extensive as would have been necessary without the treatment. Professor Bier has published a number of cases treated successfully by his method. These include "Transformation of Acute into Chronic Abscess," "Disappearance of Abscess," and cases of rheumatic, gonorrhœal, and suppurative arthritis. The following is one of the cases reported by Mr. Cathart. A man, aged 40 years, was admitted into the Edinburgh Royal Infirmary on Nov. 8th, 1905, for pain and swelling of the right hand and forearm. About a fortnight before he felt pain in the thumb which he attributed to the prick of a thistle. On Nov. 5th he was worse and an incision was made into a swelling on the ball of the thumb without relief. On admission he was in great pain, the hand was dark red and much swollen, and swelling extended irregularly up the forearm to the elbow. At 2 P.M. an elastic bandage was applied to the middle of the upper arm; at 7 P.M. he was much easier and there was no throbbing in the hand as before, and the forefinger could be moved a little at the metacarpal joint. There was great œdema of the hand and forearm below the bandage. The anxiety as to the further spread of the inflammation ceased. On Nov. 17th a slough, of about the size of a hazel nut, separated from the pulp of the thumb. On Nov. 24th an abscess on the palmar aspect of the thumb was opened. On Dec. 12th the wounds were nearly healed, although there was still some stiffness of the wrist and fingers. In another case a woman suffering from gonorrhœal rheumatism of the knee for four weeks had been treated without relief by all ordinary methods. 15 minutes after the application of the bandage the pain was relieved. She steadily improved and was able to walk about. How does the passive congestion act? Professor Bier suggests that the œdema produced has an anæsthetic action on the fine nerves. The exuded serum and leucocytes no doubt have a bactericidal action which checks the inflammation.

COUNTRY HOLIDAYS FOR LONDONERS.

THE financial support of the various institutions which have for their object the provision of a few days' holiday in the country for the children of the poor is a duty upon the well-to-do Londoner. In a city like London it is inevitable that many children should be brought up in an environment which must heavily react upon them and the ameliorating effects of a holiday in the country, though only for a few days, are undoubted. 360 days of a dreary year may be lightened by a five days' sojourn in the unwonted surroundings of the country. And the arguments used on behalf of the children can be used also for their elders. There are many poor folk in London to whom the stay among green fields for a few short days would mean invigoration to continue their arduous struggle, and though the needs of the children may come first in our minds their case is not always more urgent than that of their parents. The Bishop of London is appealing in the public press on behalf of the Women's Holiday Fund, Denison House, Vauxhall Bridge-road, S.W. For the Factory Girls' Holiday Fund, St. Peter's Rectory, Saffron-hill, E.C., we have frequently appealed, and also for the Children's Country Holiday Fund, 18, Buckingham-street, Strand, W.C. Appeals are also being made for the provision of country holidays by the authorities of the Rosemary Ragged Schools, 161, Highbury New Park, N.; by the Fox Court Ragged School and Mission, 136, Pentonville-road, N.; by the St. Thomas's, Stepney, Sunday School, the Vicarage, Arbour-square, Stepney, E.; and by the Mansfield-street

School (Secretary, 11, Fentiman-road, Clapham-road, S.W.); while Canon Allen Edwards writes with the same object from All Saints Vicarage, South Lambeth, S.W., on behalf of 3500 children. We must mention one more appeal, and in doing so may ask our readers to notice how prominent a part in the good work which we have outlined is played by the clergy. The clergy of London are many of them quite poor. For practical purposes they may be said to live the lives and bear the burdens of the humblest of the community and to them a break in their arduous routine is as welcome and beneficial as it is to any of their charges. Canon Benham is appealing on behalf of the Country Holiday Fund of the Poor Clergy Relief Corporation, contributions to which may be sent to 38, Tavistock-place, Tavistock-square, London, W.C.

THE DEATH OF MANUEL GARCIA.

A LITTLE more than a year ago—namely, on March 17th, 1905—the one hundredth anniversary of the birthday of Señor Manuel Garcia was being celebrated in London when representatives of music and science from all parts of the world assembled to do him honour. Our own Sovereign conferred upon him a Commandership of the Royal Victorian Order. Now he has passed away, having died in London on July 1st, but his memory will remain for all time, especially in the hearts of members of the medical and musical professions who owe so much to him as the inventor of the laryngoscope. As Professor Fränkel said during the Garcia centenary celebrations, "the genius of Señor Garcia has thrown light on the dark places of the larynx and the source of the living human voice."¹ Señor Garcia was born on March 17th, 1805, in Madrid, and afterwards became a teacher of singing, his three children Manuel Garcia, Madame Malibran, and Madame Viardot-Garcia following in his footsteps and becoming great musicians. The story of how he came to invent the instrument which has made his name famous has been told so many times that we need not repeat it here except to refer to the fact that the results of his investigations were presented to the Royal Society in a paper entitled "Physiological Observations on the Human Voice" which was published on March 22nd, 1855. It was on the invitation of Sir (then Dr.) Felix Semon that Señor Garcia read his paper on the invention of the Laryngoscope at the International Congress of Medicine held in London in 1881. It is interesting to note that he was the oldest honorary member of the Laryngological Society.

A NEW REVIEW OF SCIENTIFIC PROGRESS.

A QUARTERLY journal of scientific thought entitled *Science Progress in the Twentieth Century* has made its appearance under the editorial supervision of Dr. L. H. Alcock and Mr. W. G. Freeman, Mr. John Murray being the publisher. Since the lapse of *Science Progress* in 1898 there has been no journal of British science devoted to comprehensive summaries of recent work, although specialisation and multiplication of technical journals render it increasingly difficult to keep abreast of the advances of knowledge, so that even those actually engaged in scientific work seldom are able to inform themselves save in the most superficial manner of work done in other fields than their own. In the new journal, using the words of its preface, "the chemist will describe for the botanist recent advances in chemistry, the botanist will do the same service for the chemist, even it is hoped to the advantage and assistance of both," and as the summaries are to be prepared by those actually engaged in the work facts ought to be marshalled in true perspective. We wish the new venture, which starts auspiciously, every success. Its

¹ Vide THE LANCET, March 25th, 1905, p. 814.

role may be more to inform the public than the man of science, but it is important, highly important, to the cause of science that the public, now generally educated, should be able to appreciate the scope and value of scientific work. Medical men in particular feel this. Among the articles in the first number we may mention as specially interesting a paper upon Physical Geography as an Educational Subject, by Dr. J. E. Marr; one upon the Australian Mining Fields, by Mr. J. W. Gregory; and one upon the Distribution of Injurious Insects, by Mr. F. B. Theobald. Mr. Theobald's paper is calculated to mitigate the pride of the twentieth century in the strides of civilisation, for it is clearly shown that the development of methods of intercourse by means of boats and trains afforded facility for the spread over the globe of a great number of injurious insects.

KING EDWARD VII. SANATORIUM.

THE King has approved of the following appointments in connexion with the King Edward VII. Sanatorium at Midhurst. Consulting staff: Sir William H. Broadbent, Bart., K.C.V.O., F.R.S., Sir Richard Douglas Powell, Bart., K.C.V.O., Sir Felix Semon, K.C.V.O., Sir Hermann Weber, Sir Lauder Brunton, F.R.S., Dr. C. Theodore Williams, M.V.O., Professor T. Clifford Allbutt, F.R.S., Professor William Osler, F.R.S., Dr. James Frederic Goodhart, Dr. J. Kingston Fowler, Dr. Percy Kidd, and Dr. William Bulloch. Executive committee: The Viscount Esher, G.C.V.O., K.C.B. (chairman), Sir Frederick Treves, Bart., G.C.V.O., C.B. (deputy chairman), the Hon. Sidney Peel, Sir Francis Laking, Bart., G.C.V.O., Colonel Lascelles, M.V.O., Mr. William James, D.L., J.P., Mr. Rowland Bailey, M.V.O., I.S.O., and Dr. P. Horton-Smith-Hartley, M.V.O. (honorary secretary). Lady Visitors: Mrs. William James and Miss Ethel McCaul, R.R.C.

SALTS OF SILVER IN OPHTHALMIC PRACTICE.

FOR many years the only preparation of silver that was in common use in the treatment of diseases of the eye was the nitrate. Solutions of this salt containing two, five, or ten grains in an ounce of water occupied a prominent position on the table or desk of every ophthalmic surgeon who instilled a drop with a quill or brush in all forms of conjunctival inflammation and in many cases of ulcer of the cornea. Occasionally ointments of similar strengths were applied to the inner surface of the lids and now and again the solid stick of the pure or mitigated salt was passed lightly over the surface. There is no doubt that these applications were in many instances highly effective in arresting morbid processes, though their efficacy had been learned purely empirically and, of course, without the knowledge which we now possess of their mode of action. Lately efforts have been made to introduce other salts of silver into practice and a pamphlet has been published by Dr. Darier of Paris in which the chief combinations of nitrate of silver with organic compounds are set forth and warmly recommended on the grounds of their comparative painlessness when topically used and their greater power of penetration. Dr. Darier is of opinion that the bactericidal action of nitrate of silver is due to the silver base, whilst the acid with which it is combined exerts an irritant or even caustic action on the tissues as soon as it is set free by the combination of the silver with albumins of the tissues, for which it has a strong affinity. It is the liberated acid which is the cause of the irritation and pain, often very severe, which follow the employment of the watery solutions. S. Fraenkel of Vienna has suggested that a far more satisfactory mode of exhibiting the salts of silver is by combining the base with albuminous compounds. Any such compound should be

soluble in water; should occasion neither irritation nor pain; and, lastly, should not coagulate albuminous substances. Dr. Darier, in the first instance, experimented with argentamine recommended by M. de Hoor, and found that solutions of from 3 to 10 per cent. were much less painful than the ordinary nitrate solutions of equal strength. Argentamine is a solution of ethylene diamine-phosphate of silver. The ethylene-diamine which enters into the composition of argentamine is an organic base with feebly caustic properties but having the property of redissolving the precipitates which the salts of silver form in contact with the tissues. By micro-chemical research it has been shown to possess great penetrating powers. Moreover, which is of high importance in a therapeutic point of view, argentamine is much more rapidly and more surely fatal to the gonococcus than the solutions of the nitrate of corresponding strength. For all catarrhal and purulent affections as well as for trachoma it may be advantageously substituted for the nitrate. Another salt of silver of great value as an antibleorrhagic is argonin, in which silver is combined with casein, but Dr. Darier cannot recommend it with equal confidence. The sulpho-phenate of silver has been proposed by M. Zanardi as being antiseptic and but little irritant. Itrol (citrate of silver) recommended by Nénadovic is of more than doubtful value. The cornea in some instances resents its action. Collargol, both in solution and in the form of ointment, has been found serviceable in bleenorhagic affections by various authors, but Dr. Darier appears to hold that protargol is the most effective and useful of all the preparations of silver. He uses it in solution in the proportion of 1 part of protargol to 4 of water, one drop of which should be dropped into the eye every hour in cases of purulent ophthalmia.

AN AMBULANCE SERVICE FOR LONDON.

THE *Times* of June 26th contained an article on Street Ambulances, pointing out that "the somewhat tardy development of the street ambulance service for the metropolis which both the authorities of the City and of the London Council have led us to expect is a condition of things not in the highest degree creditable to the capacity for local government upon which English people are usually somewhat inclined to plume themselves." This charge, so far as it applies to the London County Council, has been answered by Sir William J. Collins, M.P., who shows that the London County Council has recognised that London is "far behind many provincial towns and most large cities on the Continent and in America in the matter of the provision of rapid ambulances for dealing with accidents and cases of sudden illness occurring in the streets." The Council, however, has not the power to spend money on street ambulances, but a "General Powers Bill" which is now before Parliament and has already passed the Commons will, Sir William Collins says, give the Council power to remove a reproach from London which the Council has recognised but has not hitherto had the power to alter. Sir William Collins concludes his letter by remarking that "the lack of such ambulance service was exhibited in the disastrous tram accident at Highgate last Saturday [June 23rd], and as a hospital surgeon I can testify that the present method of bringing injured persons into hospitals in hansoms and fourwheelers is both cruel and fraught with grave peril to the injured." We have ourselves on many occasions referred to the crying need for an efficient ambulance system for the conveyance of those injured in our streets to their own homes or to a hospital and have more than once impressed upon our readers the desirability of becoming members of the Metropolitan Street Ambulance Association, of which Mr. Reginald Harrison is president and Dr. Arthur W. James secretary.

The awakening of the London County Council in this matter is, no doubt, in a large measure due to the work done by this association which numbers among its members the presidents and many members of the Councils of the Royal Colleges of Physicians of London and Surgeons of England and members of the staffs of all the large London hospitals. It may be said, therefore, that the medical profession in London has but one mind regarding the provision of an efficient ambulance service. The whole matter of the need for, and provision of, street ambulances was admirably discussed at a meeting of the Metropolitan Street Ambulance Association held on May 2nd, 1904, and reported at length in our columns on May 7th of that year, p. 1301.

THE GREENWICH OBSERVATORY.

It is stated that the highways committee of the London County Council has received a communication from the authorities at the Admiralty in which the proposal is made to inaugurate forthwith a series of tests to extend over some time with the view of settling the question as to how far the observations at the Greenwich Observatory are disturbed by the Council's electric generating station. The investigation will be conducted by representatives of the Admiralty and of the Council which at its meeting on Tuesday last decided to accede to the proposal, appointing Sir Benjamin Baker as its expert to be present at the inquiry.

THE LATE DR. JOSEPH KÖRÖSI.

Dr. Joseph Körösi, who died at Budapest on June 23rd after a long illness, was a statistician of European celebrity. Some of our readers will no doubt remember seeing him at the Congress of Hygiene and Demography held in London in 1891, where he was one of five gentlemen representing foreign nations who spoke at St. James's Hall after the delivery of the inaugural address by his present Majesty King Edward, then Prince of Wales. On this occasion he made a long speech in English, showing an intimate acquaintance with what had been done by English workers in the field of demography and vital statistics. He also in the Section of Demography and Industrial Hygiene read a paper on the Effect of the Age of Parents on the Health of their Children. Finally, he was the bearer of an official communication from the city of Budapest inviting the Congress to hold its next meeting in that city. This invitation was accepted and the Congress met there in September, 1894. The deceased, who was in his sixty-second year, was a member of the Hungarian Academy of Sciences, Chevalier of the Order of Francis Joseph and of the Legion of Honour, Member of the Institut International de Statistique, and Director of the Statistical Bureau of Budapest.

THE Department of Public Health of Queensland, in its Plague Bulletin, No. 12, states that during the week ending May 26th no new cases were reported in either Brisbane or Rockhampton. In Rockhampton 4 cases remained under treatment but there were not any in Brisbane; in Rockhampton, of 309 rats and 31 mice which were bacteriologically examined 5 rats were found to be infected. The medical officer of health of the Cape Colony states that during the fortnight ended June 9th there were 249 rats and 160 mice bacteriologically examined, of which 2 mice proved to be plague-infected. In Hong-Kong during the week ended June 30th there were 21 cases of plague and 17 deaths reported.

We direct the attention of our readers to the fact that the council of Epsom College has an opening for the presentation of a girl to the Schools of St. Anne's Society.

Candidates must be between the ages of seven and 12 years and must be the orphan daughters of duly qualified medical men who have been for not less than five years in independent practice in England or Wales. Forms of application can be obtained at the office of the College, 37, Soho-square, London, W.

Dr. T. Gregor Brodie, professor superintendent of the Brown Animal Sanatory Institution, will deliver a course of five lectures at the University of London on the Secretion of Urine under Normal and under Pathological Conditions. The lectures, which are free, will be delivered in the physiological laboratory of the University at South Kensington at 5 P.M. on July 9th, 11th, 13th, 16th, and 18th.

Dr. Hugh J. M. Playfair has been appointed by the council of King's College, London, lecturer in practical obstetrics in the medical school.

EPSOM COLLEGE.

THE annual general meeting of the governors of Epsom College was held at the office in Soho-square on Friday, June 29th. Amongst those present were Sir William S. Church, Bart. (chairman of the council), Sir Constantine Holman, M.D. (treasurer), Sir R. Douglas Powell, Bart., K.C.V.O., Sir Dyce Duckworth, Mr. Stanley Boyd, Surgeon-General A. M. Branfoot, I.M.S., Mr. J. Paul Bush, C.M.G., Dr. William Collier, Dr. John H. Galton, Dr. F. de Havilland Hall, Mr. John H. Morgan, C.V.O., Mr. Henry Morris, Mr. Bilton Pollard, Dr. Frederick Taylor, Dr. J. Roberts Thomson, Dr. George Eastes, Dr. W. Rigden, Mr. Andrew Clark, and Dr. C. Caldecott. The secretary reported the result of the voting to be as follows:

PENSIONERS.					
Name.	Votes.	Name.	Votes		
1. Harriet Hamilton*	8392	4. Hannah Scotland ...	5127		
2. Wm. F. Phillips†	7816	5. Susannah M. Fenton ...	5117		
3. Georgina Skinnert ...	779J				

FOUNDATION SCHOLARSHIPS.					
Name.	Votes.	Name.	Votes		
1. Peter M. Braidwood ...	7794	3. Robert R. L. Williams ...	5007		
2. Arthur Chamberlayne ...	6177	4. Geoffrey J. Barrow ...	3599		

* Pugh pensioner. † Hightt pensioners.

The Secretary reported that two further vacancies for pensioners having arisen the council would that day admit the two candidates next on the list—namely, Elizabeth Sutcliffe, 4860 votes; and Rosina S. Douglas, 2129 votes.

The chairman, Sir CONSTANTINE HOLMAN, moved the adoption of the report of the council to the governors, which stated that for the year 1905 there was an excess of expenditure over income of £1426 10s., excluding the cost of special drainage works, which in the two years had amounted to about £8000. In order to meet this extraordinary outlay the council had been compelled to part with all the stocks belonging to the general purposes fund, the only remaining asset being sundry mortgages amounting to £2550. A munificent donation of £5000 had been received from a lady, of which a sum of £4000 was for the purpose of founding a scholarship and several pensions in order to perpetuate the name of Dr. Hightt of Montpellier, Bristol, the remaining amount of £1000 being a contribution to the extraordinary expenses in connexion with the drainage referred to. The council had given greater facilities for the admission of day boys, the founder of the College having intended to admit a large number, but owing to the inconvenient hours of attendance hitherto in force this intention had never been realised. Last year the school was formally inspected under the direction of the Joint Universities' Board, all the teaching arrangements being reviewed by four inspectors. Their report was most satisfactory and it was followed by recognition by the Army Council, thus enabling the school to send in candidates for the army examinations. The health of the boys had been excellent on the whole and the work and discipline had been all that could be desired. Since the

last report H. L. Ridley had been awarded the "Mayo" scholarship of £70 for four years, which is given to a boy born in the county of Wiltshire and proceeding to the University. 11 boys had passed the whole or a part of the preliminary examination for the degree of M.B. or B.S. of the University of London; three boys had passed the matriculation examination of the same University in Division 1 and 12 in Division 2; five boys had gained the higher certificate of the Oxford and Cambridge Schools Examination Board; and 36 had gained the lower certificate. The council had at last been able to make an important alteration in the dietary of the boys, meat breakfasts being now provided for all free of charge.

The adoption of the report and of the income and expenditure account having been agreed to, Sir CONSTANTINE HOLMAN, the retiring treasurer, made his valedictory speech as follows:—

LADIES AND GENTLEMEN.—Half a century is a large slice out of a man's life, and it is 51 years since, at a meeting of the Surrey Medical Benevolent Society, I took part in the negotiations with Mr. Porport for an advance of £2500 to be applied towards the initiation of Epsom College, in return for certain scholarships in perpetuity which the Society was to receive. Even before that time I had been engaged in work for the South-Eastern Branch of the British Medical Association. Thus I can say that for considerably more than 50 years I have taken an active part in the public life of the profession and for 41 of those years I was engaged in a large general practice.

A brain that has been incessantly busy about many things for so long a period cannot work on at full pressure indefinitely. Sooner or later there comes a time when a man feels that the burden which he has hitherto borne with comparative ease is becoming irksome, and when responsibilities not only lie heavy upon him but become worrying anxieties. When that time comes I hold that a man should take stock of his own powers, and, in the interest of institutions in the direction of which he takes a prominent part, should retire from the position of an active administrator—before he loses the sense of the true proportion of things and the elasticity of mind that enables him to adapt himself to changes without which there can be no progress, before his judgment stiffens into obstructiveness or relaxes into vacillation and uncertainty. The duties of the office of treasurer to Epsom College carry with them heavy responsibilities, and I may be allowed to say that I have always looked upon everything that seemed to come within the sphere of those duties as a matter of grave importance. The treasurer's burden does not grow lighter and I had reluctantly to come to the conclusion that it must be transferred to shoulders less bowed by the weight of years. I should not have resigned an office which I have held, with great pride, for 19 years had I felt any longer equal to a strain which must increase as the power to bear it diminishes.

A glance at what has happened during the time I have been treasurer may be permitted. In 1887 the council pressed me to accept office as your treasurer, and with great reluctance I consented. At about the same time I was appointed treasurer of the British Medical Association, and for three years held the two offices—a double burden I should advise no one again to undertake. When the late Mr. Wood became head master of the College I found in him a fellow worker after my own heart, and I never can adequately acknowledge the help he was always ready to give. Up to that time the moneys of the College went into one pocket, but we then decided that the funds of the charity and the school should be kept separate. Finding the niceties of the division beyond our powers, I received permission from the council to call in expert aid, and we were most fortunate in securing the help of Mr. May, who ever since has remained our trusted counsellor—one most careful, most able, and most willing to advise. I would warn my successor that Mr. May has a habit of sending to the treasurer a most courteous letter annually, after completing his audit, placing his finger with most fatal precision on the weak point of the year's balance sheet. For myself I have ever welcomed these minatory letters and where possible have acted upon them. I envy the incoming treasurer the balance sheet which he will be able to bring forward as his first offering, for it promises to be the most satisfactory we have seen for many years and I think he will be able to say that, although he is a poor man, his balance sheet is sound and to be understood by anyone who seeks to know the financial condition of the institution.

The experience gained as a member of the Council of the British Medical Association, on which I served for nearly 40 years, was most valuable to me in my work at Epsom. That experience led me on my appointment as treasurer to urge upon my council the desirability of instituting committees—school, finance, selection, and works—among which the labour of administrative work was divided. These committees, composed of picked men of the council, made inquiries and threshed out questions that had to be dealt with; their reports were printed and circulated among the members of the council who thus had the opportunity of making themselves fully acquainted beforehand with every subject which was to be considered at their meetings. So well has this system worked that I can hardly call to mind an instance in which any important amendment has been moved at a meeting of the council. I have not had an easy time as treasurer. The water-supply for a long time caused much anxiety and frequent expense; I hope the matter is now settled for all time. The bursting of the bath led to the discovery that it had never had a proper bottom; it cost us £1100 to put this right. Last, but not least, came the almost crushing calamity of a breakdown in our drainage, on the renovation of which we had to spend no less than £8000. We have now a plan of drainage laid in the best possible manner known to sanitary science of today and with the best materials. So far as human ken can reach it should serve us for many, many years to come. This expense has been paid but only at the cost of selling almost all our realisable securities.

Fortunately, there is a brighter side to the picture and on this I ask you to look with gratification at what has been done and a hope of even better things for the future. You have 27 more acres of freehold land than you had 20 years ago; you have a lower school in full work, with accommodation for more pupils; and you have a fully

equipped chemical laboratory and lecture room. Acting on the advice of the examiners, the council decided to extend the science teaching which had been started in makeshift quarters. I hope the legacy we are to receive under Dr. Corbett's will may enable my successor to make better provision for this most important department of the school work. I hope, too, that an increasing number of boys will warrant an increase in the number of masters. In view, however, of the fact that for some years we have been over-stuffed owing to the number of subjects that have to be taught, the increase in the number of pupils should be substantial. Whereas in 1887 we had 191 pupils, there are now 254, which, so far, is our high-water mark; we are, I think, justified in believing that the increase is at least partly due to the elimination from the title of the word "Benevolent" which gave rise to the mistaken notion that Epsom College was a charity school. The decision of the council to encourage the attendance of day boys was carried unanimously. Although it was the wish of our founder to attract such boys, hitherto there has been no opportunity for boys coming from any distance. It has been found possible to overcome this difficulty and I trust that the facilities for the attendance of day boys which the council has recently given will never be curtailed. Other schools welcome day boys and I may mention that a member of our council, himself a former pupil of Clifton College, has borne emphatic testimony to the fact that the presence of these boys was regarded as a source of strength to that college. It has always been a pleasure to me to keep in close touch with the teaching staff and the principal officers of the College. Needless to say, many little clouds which are, it may be, at first no bigger than a man's hand but which will darken the heavens if allowed to grow, may be dispelled by a word spoken in season. The teaching staff are a splendid body of men whose whole heart is in their work; for proof of this one need only look at the scholarships and distinctions won at the hospitals and at the universities by those whom they have trained. Of the three matrons I can only say in homely phrase that they would be hard to beat. The reformations wrought by the College matron have been of the highest value; Miss Brown, our lower school matron, who plays the part of a mother to 50 small boys, is beyond praise, whilst Miss Hassall, who has for 16 years been the infirmary matron, has never failed us in times of grave difficulty and has earned the gratitude of many an anxious parent. Mr. Lamb, whom our council knows and trusts, I have much to thank for and I cannot say enough in acknowledgment of his help. I cannot conclude without referring to the incorporation of the asylum into the school premises, at a rental, whilst the aged pensioners with augmented annuities can live where they please and pass their last years amongst friends and relatives. I have heard of nothing but satisfaction expressed at this change.

A word about the council itself may not be out of place here. I have often wondered whether the governors in general have estimated at its true value the strength of the present council of the College, to the formation of which have gone infinite care and patience. That the body contains within itself all the elements that make for efficiency, will be made apparent by a study of its composition and the balance of its parts. The council consists of leaders of the profession, teachers in the great medical schools of London, representatives of the provinces whose position entitles them to the respect and confidence of their fellows, old Epsomians and two or three gentlemen of note outside the profession. In Sir Arthur Watson, Bart., K.C., chairman of the Middlesex Hospital Committee, we have now a most valued member, who never fails us when we ask counsel of him in legal difficulties.

And now, Ladies and Gentlemen, Governors of Epsom College, it only remains for me to resign into your hands the trust you placed in me 19 years ago. From my heart I thank you for the honour then done me. I have done my best, and I hope I have not been an altogether unprofitable servant. As for my colleagues on the council, how can I find words to express my gratitude to them, who have so long trusted me with their fullest confidence, who have been so indulgent to my many shortcomings, who have borne with all my failings, and who have in every way so considerate to me? Old colleagues and dear friends, I can only say I thank you with all my heart.

Sir WILLIAM CHURCH, the chairman of the council, then proposed the following motion which was carried unanimously:—

That the governors of Epsom College desire to express the great reluctance and regret with which they accept the resignation of the treasurer by Sir Constantine Holman, M.D. They desire to record upon the minutes that during the 19 years he has held this important office the institution and the College have made uninterrupted progress, the finances of both having been placed on a satisfactory financial basis under his guidance. The governors earnestly trust that Sir Constantine Holman will be spared for many years to continue to give the council the benefit of his wide experience as a member of their body.

Sir CONSTANTINE HOLMAN thereupon proposed from the chair that Mr. Henry Morris should be appointed treasurer of the College, the proposition being carried unanimously.

Mr. MORRIS then took the chair vacated by Sir Constantine Holman and whilst thanking the governors for the honour which they had conferred upon him assured them that he would do his best for the College, in which he had always taken the deepest interest. He was one of the first boys to enter the school and he felt that this lengthened interest would instigate him to do, if possible, even better than his best for the welfare of the institution. Before resuming his seat he moved that Sir Constantine Holman should be elected a member of the council in the place vacated by himself, which proposition was carried with acclamation.

The formal business which followed included the election of members of the council for a further period of three years, a vote of thanks to, and the re-election of, the auditors, the confirmation of by-laws for the Highett pensions and

scholarship, and the passing of a cordial vote of thanks to the founder of these benefactions. A vote of thanks to the chairman concluded the proceedings.

MEDICINE AND THE LAW.

The Peculiar People.

A MAN named Cook, described as an unemployed horse-keeper and a member of the sect known as the Peculiar People, has been sentenced at the Old Bailey to nine months' hard labour for manslaughter. The case did not in any way differ from the trials for manslaughter with which we are familiar in the case of these persons when their children fall ill and die owing to medical aid not being summoned, but for the fact that on this occasion not one but two children had lost their lives. One of these, a little girl aged six years, had had measles and had died and the father upon his return from the inquest upon her body had found another daughter, aged 18 months, suffering from bronchitis and pneumonia, to which she also soon afterwards succumbed. It was mentioned at the second inquest that the "bishop" of the sect, a market gardener in Essex, was consulted and that prayer meetings were held for the two children all over that county in which the Peculiar People are found in considerable numbers. It should be added that in 1898 another death of one of his children had had for its result the binding over of the father to come up for judgment when called upon. It is very difficult to know what to do with the Peculiar People but it would become absolutely necessary to do something if the sect, which is not very small, were more numerous. They are of a class which is not open to reasoning when possessed of fanatical religious belief, and to punish them, apart from the question of religious persecution, neither "reforms" the character of men who have no criminal propensities nor deters their fellows. The only possible suggestion seems to be that special legislation for their benefit should enable their children to be taken from them forcibly and treated when ill, leaving them the opportunity to pray and, should it be practicable, to anoint in addition. The difficulty would, of course, lie in discovering cases of illness which the parents would take pains to conceal.

A Motor-car Danger.

A few weeks ago Mr. A. Owen Lankester, M.R.C.S. Eng., had a serious accident owing to the collision of a cab in which he was riding with a motor-car. The evidence given in support of the summons which followed showed that a fitting frequently to be observed upon motor-cars in London may at any time become the cause of a dangerous accident. Mr. Lankester's account showed that the motor-car, which was travelling at a moderate pace at 10 o'clock at night, seemed to steer straight for the cab and that, in his words, it "went for the cab like an avenging angel." The owner, who drove the motor-car, explained his action by saying that the plate-glass wind screen with which it was fitted at the particular spot where the occurrence happened reflected some arc lamps in such a manner that he could not see where he was going, and his evidence was corroborated as to this by an independent witness. Sir Albert de Rutzen was of opinion that the defendant should have pulled up when he found that the wind screen prevented him from seeing and imposed a fine of £5 with £3 costs. It certainly seems right that anyone choosing to drive behind a sheet of plate-glass, which from other causes as well as the reflection of street lamps may lessen his power to see his way clearly, should take the consequences when an accident results. The driver, at any rate, should have no such obstruction in front of him and all such apparatus lays its user open to the observation that it is only necessary when there is an intention to drive at a speed considerably exceeding that of horsed vehicles.

The Trial of Mr. G. R. Adcock.

The trial of Mr. George Robert Adcock, M.R.C.S. Eng., L.R.C.P. Lond., indicted at the Old Bailey for the manslaughter of Major John Nicholas Whyte, D.S.O., ended last week in the jury disagreeing and being discharged without arriving at a verdict. The case has been fully reported in the newspapers and has excited widespread attention because of its sensational events, with the result that the real questions at issue have been obscured. The facts show briefly that having met with a

hunting accident and fractured his spine Major Whyte underwent an operation performed by Sir Victor Horsley, under whose care and under that of other medical men he was at one time making fair progress towards recovery, the measure and duration of the recovery being necessarily a matter of opinion. At this time there was no reason to anticipate that his life would be endangered, when falling in with a person professing belief in "Christian Science" he allowed himself to be persuaded to dismiss his medical attendants and to submit himself to the ministrations of "Christian Science healers." In their hands an ordinary sequence of preventable complications ensued and he died a lingering and painful death from blood poisoning. At a certain point in the later stages of his illness Mr. Adcock undertook duties of some kind in connexion with his case, the nature of the duties thus undertaken constituting the principal question which the jury had to decide at the recent trial. Mr. Adcock was formerly a practising medical man and had a respectable amount of practical experience. Recently he had, however, abandoned medical practice under the influence of "Christian Science," these tenets having, he said in evidence, cured him of the morphine habit. If Mr. Adcock behaved in connexion with the deceased as apparently he did behave, being a medical man, and after being called in to treat him as such, his trial upon the charge of manslaughter would have been considerably simplified. But it was urged in his defence that Major Whyte had declined to have anything to do with anything but "Christian Science" and that Mr. Adcock had professed to supply, and had supplied nothing more than, "Christian Science" aid. The jury accordingly had to determine whether there existed between Mr. Adcock and the deceased the relations of medical man and patient, and if so whether by neglecting to use ordinary care and skill the former had been guilty of a breach of duty which had accelerated the death of the latter. Upon these points they failed to arrive at a unanimous conclusion and the case has been adjourned until the next sessions. Mr. Justice Bigham, the judge before whom the case was heard, has since publicly stated his opinion that a conviction would be undesirable and that the evidence was not sufficient to bring guilt home to the man. It rests now with the Attorney-General to decide as to what course the prosecution will pursue. In the circumstances comment upon the trial is, of course, out of the question.

Looking Back.

FROM

THE LANCET, SATURDAY, July 5th, 1928.

MERCURY USED AS A PREVENTIVE AGAINST THE PLAGUE.

M. MOREAU DE JONES has communicated the following information to the Royal Academy of Sciences, of Paris. An Ionian boat having had intercourse with a Turkish vessel, the master of the boat became affected with plague, and in this state arrived at Cephalonia, where he and the boat's crew were put into the Lazaretto. The English surgeon of the Lazaretto, conceiving that the crew of the boat had received the contagion, put them all, to the number of twelve, on an active course of mercury, internal as well as external. The whole of the boat's crew were successively attacked with plague, but with a remarkable difference in the degree of intensity. The master, and one of the crew, who had not experienced any sensible effect from the mercury, died of the disease. The other ten became salivated, and had the disease in a mitigated form. They all recovered.

This remarkable event, says M. De Jones, naturally leads us to conclude that the escape of ten out of twelve was owing to the influence of the mercury; a conclusion strengthened by the fact that the two who died could not be brought under mercurial ptyalism. He observes that mercury was administered in the plague which desolated Malta in 1818; but it was given during the existence of the disease with the hope of curing it, and not as a prophylactic—which makes a great difference in the result. M. De Jones recommends mercurial frictions to be used in preference to the internal use of mercury, as a preventative, the former not being liable to objection on the score of irritating the stomach and bowels.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following are some of the principal amounts, additional to those already announced in THE LANCET, received at the Mansion House up to Tuesday evening, when the sum paid in was about £34,000.

	£	s.	d.
St. Peter's, Vere-street, per Canon Page-Roberts	613	0	0

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8441 births and 3762 deaths were registered during the week ending June 30th. The annual rate of mortality in these towns, which had been equal to 12.9 and 13.2 per 1000 in the two preceding weeks, fell last week to 12.4, a considerably lower rate than on any previous week of this year. During the 13 weeks of the past quarter the death-rate in these towns averaged only 14.9 per 1000; in London the rate in the same period was even slightly lower—namely, 14.8. The lowest death-rates during last week in the 76 towns were 5.2 in Tottenham, 6.4 in East Ham, 6.6 in Hornsey and Reading, and 6.8 in Grimsby; the rates in the other towns ranged upwards to 16.2 in Halifax, 16.3 in Manchester, 16.7 in Ipswich, 18.2 in Middlesbrough, 19.2 in Oldham, and 21.5 in South Shields. The 3762 deaths in the 76 towns showed a decline of 253 from the low number returned in the previous week, and included 372 which were referred to the principal epidemic diseases, against 372 and 380 in the two preceding weeks; of these, 126 resulted from measles, 74 from diarrhoea, 62 from whooping-cough, 57 from diphtheria, 32 from scarlet fever, 21 from "fever" (principally enteric), and not one from small-pox. The deaths from these epidemic diseases were equal to an annual rate of 1.2 per 1000 in the 76 towns the same rate prevailing in London. No death from any of these epidemic diseases was registered last week in Bournemouth, Southampton, Northampton, Ipswich, Devonport, or in eleven other smaller towns, whereas they caused death-rates exceeding 2.5 per 1000 in Liverpool, Leyton, Manchester, Salford, Halifax, and Burnley. The highest death-rates from measles occurred in Huddersfield, Leyton, Manchester, Halifax, and Burnley; from diarrhoea in Handsworth and Wigan; and from whooping-cough in Bootle. The fatal cases of diphtheria showed the largest proportional excess in Salford and Hull; and scarlet fever caused six deaths in Sheffield, five in London, and three in Manchester. The 21 deaths from "fever" showed a further increase upon the low numbers returned in recent weeks, and included nine in London and two in Liverpool. The 11 cases of small-pox under treatment in the Metropolitan Asylums hospitals at the end of last week were fewer by two than the number at the end of the previous week, no new case having been admitted during the week. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday, June 30th, was 2752, showing a further increase of 60 upon recent weekly numbers; the new cases admitted during the week were 366, against numbers increasing from 312 to 380 in the four preceding weeks. The deaths referred in London to pneumonia and other diseases of the respiratory organs, which had steadily declined in the ten preceding weeks from 399 to 137, further fell last week to 132 and were 33 below the

corrected average for the corresponding week in the four preceding years 1902-05. The causes of 41, or 1.1 per cent., of the deaths registered in the 76 towns during the week were not certified either by a registered medical practitioner or by a coroner; in London the cause of but two of the 1060 deaths were not duly certified. All the causes of death was duly certified in Manchester, Leeds, Bristol, Bradford, Newcastle-upon-Tyne, and in 50 other smaller towns. The proportion of uncertified deaths showed, however, a marked excess in Reading, Birmingham, Liverpool, Bootle, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 15.6, 15.8, and 16.0 per 1000 in the three preceding weeks, declined to 14.5 in the week ending June 30th, which exceeded by 2.1 the exceptionally low rate in the 76 large English towns but was considerably lower than the rate in these Scotch towns in any previous week of this year. The rates in the eight Scotch towns last week ranged from 11.9 and 12.0 in Aberdeen and Leith, to 15.2 in Dundee and 21.1 in Perth. The 497 deaths in the eight towns showed a decline of 50 from the number returned in the previous week, and included 22 which were referred to diarrhoea, 11 to measles, 10 to "fever," nine to whooping-cough, six to diphtheria, three to scarlet fever, and not one to small-pox. In all, 59 deaths resulted from these principal epidemic diseases, showing a decline of 10 from the number in the previous week; they were equal to an annual rate of 1.7 per 1000, which was 0.5 above the mean rate during the week from the same diseases in the 76 English towns. The 20 deaths attributed to diarrhoea in the Scotch towns were five fewer than those in the previous week and included nine in Glasgow, seven in Edinburgh, and three in Aberdeen. Of the 11 fatal cases of measles seven occurred in Glasgow and three in Edinburgh; and of the 10 deaths referred to "fever" nine were returned in Glasgow, of which latter eight were certified as fatal cases of cerebro-spinal fever. Of the nine deaths from whooping-cough four were returned in Glasgow and three in Aberdeen; and of the six from diphtheria four in Glasgow and two in Edinburgh. Two of the three fatal cases of scarlet fever occurred in Glasgow. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 95, 80, and 69 in the three previous weeks, further declined last week to 64, and were four below the number returned in the corresponding week of last year. The causes of 19, or 3.8 per cent., of the deaths registered in the eight towns last week were not certified, the proportion of uncertified deaths in the 76 large English towns during the same week being only 1.1 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 16.4 and 20.2 per 1000 in the two preceding weeks declined again to 16.4 in the week ending June 30th. During the 13 weeks of the past quarter the death-rate in the city averaged 21.4 per 1000, against 14.8 in London and 17.1 in Edinburgh. The 119 deaths of Dublin residents during last week showed a decline of 28 from the number returned in the previous week, and included two which were referred to "fever," two to diarrhoea, one to whooping-cough and not one to measles, scarlet fever, diphtheria, or small-pox. These five deaths from epidemic diseases were equal to an annual rate of but 0.7 per 1000, the rate from the same diseases being 1.2 in London and 2.3 in Edinburgh. The two fatal cases of "fever" in Dublin last week showed an increase upon recent weekly numbers. The 119 deaths from all causes in Dublin included 12 of infants under one year of age and 27 of persons aged upwards of 60 years; both these numbers showed a considerable decline from those returned in the previous week. Three inquest cases and three deaths from violence were registered, and 42, or 36 per cent., of the deaths in the city occurred in public institutions. The causes of four, or 3.4 per cent., of the 119 deaths were not certified by a registered medical practitioner or by a coroner, the proportion of uncertified deaths being but 0.02 per cent. in London and 3.1 in Edinburgh.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Deputy-Inspector-General J. O. B. Williams to Chatham Hospital (temporary). Surgeon E. R. Townsend to the *Sapphire*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel William T. Johnston retires on retired pay (dated July 4th, 1906).

Lieutenant-Colonel W. L. Reade, from Bangalore, takes over the office of Senior Medical Officer, Madras Brigade. Captain S. A. Archer is appointed for duty in the Dublin district.

INDIAN MEDICAL SERVICE.

Colonel T. J. H. Wilkins, principal medical officer of the Burmah Division, has been transferred to the Secunderbad Division as principal medical officer, vice Colonel A. F. Dobson, retired; Lieutenant-Colonel W. O'Hara has been appointed principal medical officer, Bangalore and Southern Brigades; and Lieutenant-Colonel N. Chatterjee has been appointed to officiate as principal medical officer of the Burmah Division.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain John S. Mackay to be Surgeon-Major (dated June 23rd, 1906); Surgeon-Lieutenant Leonard A. Avery to be Surgeon-Captain (dated June 24th, 1906).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Cheshire: Surgeon-Major A. M. Archer is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated June 29th, 1906). Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel A. M. Archer resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated June 30th, 1906).

Rifle: 1st Volunteer Battalion the Leicestershire Regiment: William Frederick McAllister-Hewlings (formerly Captain) to be Surgeon-Lieutenant (dated June 30th, 1906).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Gloucester and Somerset Bearer Company: Captain A. W. Dalby to be Major (dated June 30th, 1906).

THE BIRTHDAY HONOURS.

The list of Birthday Honours included the names of Deputy Surgeon-General John McNeale Donnelly, C.B., I.M.S., retired, and Surgeon-General Alfred H. Keogh, C.B., Director-General of the Army Medical Service, who have been promoted to be Knights Commanders of the Bath; of Surgeon-General W. Simon Pratt, A.M.S., P.M.O. of the Southern Command; and Colonel H. Kellock M'Kay, C.I.E., I.M.S., who receive Companionships of the Bath; and of Lieutenant-Colonel David Prain, I.M.S., Director of the Botanical Survey of India, who is made a Companion of the Order of the Indian Empire.

RESERVISTS AS SANITARY INSPECTORS.

Dr. J. S. Purdy writes to us as follows: "If the Local Government Board recognised a diploma in Sanitation gained by a non-commissioned officer in the army by passing an examination equivalent to that prescribed by the Sanitary Institute I am sure that not only would the country benefit by reservists being eligible for appointments as civil sanitary inspectors but also great encouragement would be given to the study of hygiene in the army, more especially among the men of the Royal Army Medical Corps. One of the most efficient sanitary inspectors I ever knew was an ex-sergeant, *some* diploma, at Tottenham. Men trained in the army are disciplined and do what they are told, and do not as civilians are more apt to do, show a tendency either to pose as amateur experts on medical subjects or exceed orders. In a recent conversation with Colonel Hamilton, I.M.S., he expressed himself as favourable to the idea, so I trust that other men in the Army Medical Service will assist in bringing the subject to the notice of the authorities. The fact that a course of hygiene at the Royal Army Medical College qualifies an officer to sit for the D.P.H. ought to be sufficient precedent for allowing a non-commissioned officer of the same corps to sit for the sanitary diploma prescribed for civil inspectors." There is sound good sense in Dr. Purdy's views. And the more our army, from top to bottom, becomes familiar with the precepts of sanitary teaching, the

greater will be the chances of the men escaping during times of war from the horrors of epidemic disease. We understand that Colonel Hamilton intends to bring the subject before the War Office.

MEDICAL SCIENCE IN WAR.

Mr. Brodrick's letter to the *Times* of June 6th under the heading of "Medical Science and Military Strength" did good service in arousing public attention and in eliciting some strong expressions of opinion as to the limitations under which medical science labours in actual war. While gratefully recognising the great services which the late Secretary for War had rendered in the way of improving the Royal Army Medical Corps we said that the Army Medical Service was still not an ideal one. In Mr. Brodrick's scheme the Director-General of the Army Medical Service had a place on the Army Council. He has since been relegated to a far more subordinate position in the Adjutant-General's Department. Now everything in war depends upon preparedness and the views and recommendations of the medical service on questions of such importance as the sanitation and health of the army in preparation for war should be of a direct and personal kind and not have to be filtered through any one of the heads of departments. The functions and responsibilities of a director-general as the representative of the Army Medical Service are of an altogether exceptional and responsible kind, and nowadays, as we all know, it is not the adjutant-general or head of any other War Office department who is blamed in case of any medical failure in a campaign but the medical service itself. Although it may have had an amount of responsibility out of all proportion to any power which it may have possessed to alter or to control the course of events, the medical service may confidently count upon having all, or an undue share, of any blame in the future. Army retrenchment is apparently the order of the day but the present Secretary of State may still give heed to the lessons of our past medical experience in war and make some announcement thereon in his forthcoming statement about the army.

JOURNAL OF THE ROYAL ARMY MEDICAL CORPS.

The June number of this journal, edited by Colonel David Bruce, R.A.M.C., C.B., F.R.S., is a very good one. It contains a number of papers on a variety of subjects of scientific, army medical, and current interest, together with the usual corps news.

NEW CHIEF FOR RUSSIAN MILITARY MEDICAL ACADEMY.

The committee of senior ordinary professors has chosen A. Ya. Danieliefsky, now occupying the chair of Medical Chemistry, as principal of the Military Medical Academy. The *Pharmazeviticheskii Journal* adds to this information that Professor Danieliefsky was a student in the Imperial University of Kharkoff. He was appointed Extraordinary Professor of the University of Kazan in the chair of Medical Chemistry and Physics in 1865. After being transferred to the chair of Pharmacology in 1868 he again took the chair of Physiological Chemistry. He was professor of Medical Chemistry in Kharkoff from 1885 to 1892, since which year he has occupied a similar position in the Military Medical Academy.

Major F. A. Saw, R.A.M.C., who has recently retired on retired pay, served in the operations in South Africa under Sir Frederick Carrington in medical charge of the Mashonaland Field Force, which suppressed a native rebellion in 1896 (medal and clasp), and also during the campaign of 1899 to 1901 (medal and clasp). At the fight at Stormberg we understand he brought in the wounded in the only ambulance wagon then available.

INTERNATIONAL EXHIBITION OF HYGIENE, MONTEVIDEO.—We are informed by the Consul-General for Uruguay that an International Exhibition of Hygiene will be annexed to the Third Latin-American Medical Congress, to be held in Montevideo, in the Republic of Uruguay, from Jan. 13th to 20th, 1907. The exhibition will last two months and will comprise exhibits of apparatus, models, foods and drinks, industrial, chemical, and pharmaceutical products, medical, surgical, and orthopedic apparatus, and industrial processes relating to hygiene and presented for commercial purpose. Firms wishing to register their names as exhibitors should apply by writing to the Secretary-General of the Congress, Palacio del Ateneo, Montevideo, before Sept. 1st.

Correspondence.

"Audi alteram partem."

THE CAUSES OF LEPROSY.

To the Editors of THE LANCET.

SIRS,—I have to thank you warmly for the able and comprehensive review of my book on Leprosy which appeared in THE LANCET of June 16th and also for your very kindly references to myself. The spirit of candid inquiry and of desire for the truth which your article manifests encourages me to hope that you will not be unwilling to allow me to answer briefly the objections which your reviewer specifies against the creed which I advocate. Several of my critics who have avowed themselves not wholly convinced have been content with the vague statement that there are weak points in the arguments, without naming any one of them. You have, on the contrary, in a manner which shows much familiarity with the subject, stated clearly in what respects the suggestion of the fish-food causation of leprosy appears to be unsupported by facts. I am especially glad that this has been done, because I feel confident that only a very few words of explanation as regards each several allegation are needed.

To take first the statement that Dr. Francis Day whilst travelling in Burmah never saw a case of leprosy although the Burmese are fond of fish. The simple fact is that although Dr. Day did not see them there were plenty if they had been looked for. I answered Dr. Day's most careless statements a quarter of a century ago. He made the same assertion as regards the Straits Settlements at a time when in reality there were many lepers there. Dr. Day was a good naturalist and an authority on fish, but he did not inquire as to leprosy. It is easy enough for a traveller to see nothing of this disease unless he searches for it, and others besides Dr. Day, even some who have resided long in Burmah, have made similarly absurd statements. There is, however, not the slightest doubt as to the facts. The Burmese eat much bad fish and they have a great deal of leprosy.

In reference to Dr. Vincent Richards's conclusions I have much pleasure in agreeing with you that he was an able and painstaking inquirer but he collected his statistics on the erroneous assumption that if leprosy were due to fish it ought to prevail most where fish food is most abundant. Paradoxical as at first sight it may appear, there are many conditions in which the reverse is true. It is not the quantity but the quality of the fish which is in question. Dr. Richards wrote two reports. Your reviewer has perhaps seen only the first. In the second he admitted that the facts "certainly seem to indicate that the consumption of fish does exercise some influence in producing the disease."

As regards the Sandwich Islands, the balance of evidence is, I believe, to the effect that in them, as in most of the Pacific groups, leprosy has always been an indigenous disease. I may admit, however, that it did not prevail extensively until the advent of Europeans and Chinese, and also that prior to that advent a great deal of fish was eaten. Let us ask, however, in what condition was it eaten? As your reviewer is careful to state "especially raw." Now, fresh raw fish is not suspected as a cause of leprosy, and it is on record that the islanders never practised fish-curing in any form and that they would eat their fish as soon as taken out of the water and almost before it was dead. It was the immigrant Chinese and Europeans who introduced the practice of curing, and it is very possible that some of the Chinese may have been lepers and may have tainted the food which they handled. At any rate they introduced the practice of fish-curing with all its risks.

I will not say anything more as to the denials of fish-eating by Indian lepers and others, than that I think that I have produced sufficient evidence that their statements are not in the least trustworthy (see page 155 *et seq.*). You write, quite correctly, that "caste ordinances again militate against the use of fish in many who have become lepers." It is true that they do "militate against it," but they do not wholly prevent it, and it is unquestionable that throughout India the castes which are professedly vegetarian suffer far less than others.

You cite the well-known case recorded by Dr. Benson and those by Professor W. Osier as if they were proofs of the

occasional contagiousness of leprosy. If, however, we make a clear distinction between skin-contagion and communication by the mouth, are they of any value? Is it not in the Dublin case quite likely that the brother who contracted the disease, as is supposed, from wearing his leprosy brother's clothes, also exposed himself to risk by taking food which had been touched and contaminated? The two brothers lived together in a peasant's cabin and very probably used the same drinking vessels, knives, spoons, &c. The possibility of skin contagion—which perhaps ought alone to be called "contagion"—is discredited by a thousand facts, whilst the reality of mouth-communication (i.e., by food) is, I think, doubted by none. To which then ought we to refer these very exceptional facts?

As regards the failure or otherwise of segregation measures, it is too large a subject for me to discuss in a letter. I must be content to observe respecting the asserted increase in Madagascar that it may have been due to increased facilities for the transport of fish. I possess a good deal of information as regards that island but there is scarcely any place in the world from which I should less hopefully expect any trustworthy data as to the prevalence and causes of leprosy. It has been asserted respecting many other places that the disease increased when segregation was neglected but the fact is that it has often died out under absolute neglect of it and as often thriven in spite of its energetic enforcement. It is increasing now in Cape Colony, &c., in spite of the enforcement of cruel laws and it is steadily dying out in Norway although the number of those segregated has been diminishing. In the latter country registration and good advice as to eating, &c., would appear to be all that is needed. The leper is allowed to remain at home with his friends and the miseries of such places as Robben Island are unknown there.

I am, Sirs, yours faithfully,

June 30th, 1906.

JONATHAN HUTCHINSON.

HYGIENIC MEASURES AGAINST SYPHILIS.

To the Editors of THE LANCET.

SIRS,—In Dr. B. Leppington's criticism of Professor Metchnikoff's third lecture (on syphilis) it is possible to agree with him in his warnings as to the incompleteness of the experiment. Dr. Leppington, however, speaks of Professor Metchnikoff's "parrot's" cry "that hygiene must be paramount over morality" and then asks what Professor Metchnikoff means by morality? He answers, Professor Metchnikoff "evidently means that the combat with disease is to be unflinchingly carried on by means which involve a definite deterioration of public morality." Dr. Leppington then says "the supreme ally of the hygienist is a rising level of morality, which by diminishing the area of vice diminishes the difficulty attending the campaign against the consequences of vice," and finishes by saying "that every hygienist who casts contempt against virtue is adding to the momentum of forces against himself." The implication of all this is that Professor Metchnikoff is engaged in a work that will lead to a diminished public morality; that he regards virtue of little value, and thus in the end will defeat his own aspirations.

Professor Metchnikoff needs no one to defend him, but Dr. Leppington's own views may be examined. He alleges (without proof) that the disease he is dealing with springs largely out of moral weakness. Does it? I am prepared to deny this. What is morality? Is it not the habit or way of life which conduces to the well-being of society and "ultimately is a matter of organisation, of instinct rather than of ratiocination? A knowledge of moral precepts, whether culled from works on ethics or heard in sermons, never made people moral, and never will. It is the ever present forces of life, heredity surroundings, that determine conduct, and the only way of affecting conduct for the better is by modifying the influence on human nature of those forces that are persistent and inescapable."

It may be very flattering to those of us who have not contracted syphilis and who have not perhaps been where it could be acquired to regard ourselves as morally strong. But our every action is governed by inflexible laws. The man with strong desires, whose motives to gratify those desires are stronger than any other he possesses, will gratify them so long as there is an opportunity irrespective of the consequences. The man whose desires are not so strong,

whose dread of the consequences is greater than any pleasure he would derive from gratifying them, will not do so, but it is beside the question to say the one is morally strong and the other morally weak. It is sheer wrong-headedness not to recognise the fact that we cannot end the desires of either sex and that all we can do where their gratification leads to disease is to limit the baneful effects as much as possible.

The question now arises, Who people the places where syphilis can be contracted? Not men who are morally weak (whatever that means) but men whose sexual desires are strong. As for the women, let Dr. Leppington read the words that Mr. Upton Sinclair in "The Jungle" puts into the mouth of Marija. We have it also on the authority of Lady Jeune that women sell their bodies for bread. So long as our present social conditions continue crushing and condemning millions to starvation so long will there be bodies for sale. The true remedy is that which shall prevent poverty and the day of that remedy is coming, is nearing, is at hand. For the present, however, we are restricted to "regulation" or "abolition." If it can be shown that "abolition" diminishes the amount of syphilis we should all be abolitionists. If, however, it simply serves to scatter the disease far and wide on the innocent as well as the "guilty," surely we should all be "regulationists." But it may be argued that that is legalising vice. It may be so, but we have had to legalise drinking and other "vices." It is also said "inspection" demoralises, but it is sheer silliness to say that one who has to submit to the embraces of a dozen strangers every night is demoralised by the visit of a medical man once or twice a week. What, then, of the morality, or rather immorality, of those who, like Dr. Leppington, because regulation does not stamp syphilis out, are prepared to let each unfortunate act as a focus of disease in the district in which she lives, infecting and damning innocent women and children? Surely the unborn have the strongest claim upon us because of their innocence and helplessness. It is not necessary to despise those of our sisters who have to submit to inspection—the man who does so shows he has much to learn. We can feel for them and the stronger we feel the harder we will work for the abolition of that competitive system which is flinging millions on the street. Till that day dawns when the evils we speak of will have righted themselves no one has a right to speak of men like Professor Metchnikoff as casting contempt against virtue. The immoral man is not Professor Metchnikoff but he who would so order things as not to lead to the highest well-being of society.

I am, Sirs, yours faithfully,

Liverpool, July 1st, 1906.

C. R. NIVEN.

THE ALLEGED GROWTH OF INSANITY.

To the Editors of THE LANCET.

SIRS,—Dr. D. Nicolson in an interesting and suggestive letter published in THE LANCET of June 9th quotes from the last annual report of the Commissioners in Lunacy a statistical statement with reference to the increase in the number of the insane under their surveillance in England and Wales between Jan. 1st, 1869, and Jan. 1st, 1904—namely, from 53,177 to 119,829. The sentence containing this statement quoted by Dr. Nicolson is: "In spite of this large numerical increase, it will be found that when considered in relation to the growth of population the proportion of insane has not increased as much as the population." Your correspondent states with regard to this quotation: "With this definite expression of opinion on the part of those who are in the best position to know I am content to leave this aspect of the question." I do not, of course, presume to judge what precise signification Dr. Nicolson attaches to what he describes as a "definite expression of opinion" by the Commissioners in Lunacy, but it seems more than probable that this, to me, meaningless statement of the Commissioners might lead many to believe that the rate of increase of the insane under their control between 1869 and 1904 was not so great as the rate of increase of the population. What are the facts of the case as stated by the Commissioners? The numerical increase of the insane during these 35 years was 125.3 per cent. and the numerical increase of the population during the same period was only 53.6 per cent. Thus the number of the insane increased more than twice as rapidly as the population. If, however, the increase of population be taken into

account, the ratio or proportion of the insane to the population showed an increase of only 46.6 per cent. during the 35 years. Any attempt to compare the numerical increase of the population with the increase in the ratio of the insane to the population is not only statistically fallacious but is absolutely meaningless.

We are faced with the grave fact that the ratio of the insane under the control of the Commissioners in Lunacy to the population of England and Wales showed an increase of 46.6 per cent. during the 35 years under notice and this fact has to be met and explained by those who, like Dr. Nicolson and myself, believe that it does not necessarily imply an increasing rate of occurring cases of real insanity.

I am, Sirs, yours faithfully,

Surbiton, June 28th, 1906.

NOEL A. HUMPHREYS.

THIOSINAMINE INJECTIONS.

To the Editors of THE LANCET.

SIRS.—In the report of the meeting of the Dermatological Society of London in THE LANCET of June 30th, p. 1833, there is an error as to duration of the treatment by thiosinamine injections of the hypertrophied scars resulting from serious burn. The case was treated by me for two years, not five. The results have been excellent.

I am, Sirs, yours faithfully,

Harley-street, W., June 30th, 1906.

GEORGE PERNET.

CEREBRO-SPINAL FEVER.

To the Editors of THE LANCET.

SIRS.—In THE LANCET of June 30th, p. 1860, reference was made to the memorandum recently issued by the health committee of the Glasgow town council on the above subject and with your permission I should like to extend the description of the rash there given in the light of a recent observation. As stated in my memorandum two of the cases therein described presented in addition to herpes on the lips "a few spots petechial in character, few in number, and irregularly distributed more pronounced than a typhus rash, and much more limited in distribution." This description was taken from two cases, which alone of those within my knowledge at the time presented anything of the nature of a rash.

During last week, however, there was admitted to Belvidere Hospital a child, aged seven months, in whom the features of a typhus rash were exactly reproduced within limited areas of the skin—that is, on the fourth day from the onset of the symptoms a rash was present which in areas of the skin of the thighs and abdomen limited to about two palms' breadth appeared to Dr. J. Brownlee, the physician-superintendent, and to myself to present no features by which it could be distinguished from that of typhus fever. It had the appearance of a subcuticular stippling which could be obliterated on pressure and it was only on looking beyond the limits of these areas that discrete purpuric spots could be observed such as alone had been present in the cases described in my memorandum and which bore no resemblance to any of the features of a typhus rash. The subcuticular stippling in the latter case was pretty generally distributed.

I shall be glad if you can find room to insert this in an early issue.

I am, Sirs, yours faithfully,

Glasgow, July 3rd, 1906.

A. K. CHALMERS.

THE CONDITION OF THE VESSELS DURING SHOCK.

To the Editors of THE LANCET.

SIRS.—I should like to be allowed to make some remarks on Mr. W. Sheen's paper,¹ in which he suggests a theory that might bring the views I have advanced² on the condition of the blood-vessels during shock into harmony with those of Dr. W. G. Crile, as so ably set forth and supported by Mr. J. P. Lockhart Mummery³

Mr. Sheen, as I understand him, agrees with me that the

superficial vessels are not dilated during shock and his theory is that their condition may be one of relaxation without extension. He suggests that a pressor action first occurs. Afterwards "the vaso-constrictor impulses pass off and vaso-dilator impulses reach the vessels. But they cannot dilate, because there is no blood to fill them, the blood being already accommodated in the portal system and elsewhere."⁴ That the vessels might be paralysed but not dilated seems to me the only possible explanation of the phenomena observed, if the vessels are paralysed. But shock, as I have observed it, has usually been induced slowly. Hence, by Mr. Sheen's view, it must be believed that the blood gradually collects in the internal areas and Dr. Crile asserted that the blood pressure became raised in the portal vein. If at the same time the systemic vessels become paralysed but do not dilate the conditions must be eminently calculated to lower the resistance to the blood flow in the systemic vessels as compared with that in the vessels of the splanchnic area. According to this view the question why, in the circumstances, the blood does not flow in the direction of least resistance so as to fill the systemic vessels seems still to require an answer.

This matter is of very great practical importance, if only because of its bearing on the administration of stimulants. Mr. Sheen does not state his view of this question, but according to Dr. Crile's theory the administration of alcoholic stimulants (vaso-dilators) is harmful during shock and the application of warmth to the surface of the body is of very doubtful utility; indeed, theoretically it also is harmful. On the other hand, if my view is right warmth and vaso-dilators are useful in theory, as I believe them to be in practice.

I am, Sirs, yours faithfully,

July 2nd, 1906.

JOHN D. MALCOLM.

ARMY NURSING.

To the Editors of THE LANCET.

SIRS.—I have read with a great deal of interest all the articles which have appeared in THE LANCET and elsewhere¹ the "Queen Alexandra Imperial Nursing Service." As a surgeon who has had some experience of civil hospitals in this country and had a good deal to do with the management and training of nurses in colonial hospitals, as well as some unique experience both in the field and in a general hospital during the late South African War, it seems to me a great pity that there should be any falling off of male nurses in the Royal Army Medical Corps. Everyone will, of course, admit that lady nurses are absolutely necessary in military hospitals, but that is not the point. They can be recruited very largely from the large civil hospitals and from among those who have been trained in them, where it must be allowed that the nurses have a far larger field and opportunity for training than can exist in military hospitals. With regard to the male nurses, however, the case is altogether different. During war time the exigencies of the service require that the whole of the nursing at, or close to, the front should be in the hands of male nurses. There are few, if any, institutions which train male nurses and none so efficiently for the special work required of them in time of war as the military hospitals. As great a number of the men as possible of the Royal Army Medical Corps should consequently be encouraged to become efficient nurses. We should then get a large number of competent male nurses and not be left in the dire position that fell to my lot of having during a small siege lasting 12 days over 70 casualties in the first five days without the help of a single man who could even put on a bandage, as no medical orderlies could be spared to accompany that force.

I am, Sirs, yours faithfully,

July 2nd, 1906.

D.S.O.

⁴ THE LANCET, loc. cit., pp. 1825-26.

AN UNFOUNDED CHARGE.—At the Gloucestershire quarter sessions, held on June 28th, Mr. George Norman Robbins, L.R.C.P. Lond., M.R.C.S. Eng., surrendered to his bail to answer a charge of having committed an assault on a girl, aged six years, on March 18th last. The case was gone into at the 1st sessions but the jury could not agree. Without leaving the box the jury unanimously returned a verdict of "Not guilty," which was received with applause, and Mr. Robbins was warmly congratulated by his many friends in court.

BUSACO AND THE FUTURE OF PORTUGUESE HEALTH RESORTS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

It is only natural that the Portuguese should expect some return for the very great and, as it proved to be, the successful effort which they made to receive worthily the Fifteenth International Congress of Medicine. The advantage that may legitimately be expected to accrue from this endeavour is that their country will be better known and appreciated by other nations. Henceforth, it is anticipated, more interest will be manifested abroad in regard to Portugal. Then as it was a medical congress which the Portuguese organised, and as medical men often have to give advice in regard to health holidays, wintering abroad, &c., it is thought that a tour in Portugal may now be more frequently suggested. It will, therefore, not be out of place to inquire how far this is likely to be the case and whether there are any obstacles to the full realisation of such a prospect. At the same time, it must be noted that before the Congress met at Lisbon the number of visitors to Portugal was increasing. Nevertheless, there can be no doubt that if the resources and the attractions of the country were better known the visitors and tourists would be counted not by hundreds but by thousands. Indeed, if it were possible to do in Portugal what has been done on the Riviera, in Switzerland, and in many of the other well-known pleasure and health resorts, there is no doubt that many thousands of British, American, German, and other tourists would annually visit the country and that to many invalids such a journey would be of great benefit. Unfortunately, the Portuguese are not a business-like people. They are capable of acquiring a considerable amount of theoretical knowledge but seem to be singularly deficient in practical sense. If this were not the case they would surely manage their own business themselves instead of calling in so much foreign aid, not merely financial aid, but that of technicians. At the same time it is to the credit of a people not to attempt that for which they are manifestly unfit. This was the secret of Japan's success. The Japanese resorted to foreign technicians till they had learnt from them all that was worth knowing.

Though the fact is not perhaps generally realised the creation of a health resort is a technique or rather a combination of many techniques. Then just as, for instance, Lancashire stands first in the world for all that relates to the technique of the cotton industries, so do the Swiss stand first in regard to the technique of hotel management and of that vast industry appropriately qualified in some French guide books as "the exploitation of the foreigner." The Riviera was not created by the natives of the Riviera, but by Swiss and German hotel-keepers, by capitalists and enterprising people who came from all parts, but especially from the north of Europe. The practical question to-day is therefore, How would the promoters of such enterprises fare in Portugal? Would they be allowed to bring prosperity to the country? The little I have seen in this respect is not altogether encouraging. There was so much to do in regard to the medical congress that I could not attempt a regular investigation as to the prospects of the health resorts of Portugal but I determined at least to visit the most remarkable spot of the entire country. This is undoubtedly the estate of the old Carmelite Monastery at Busaco. When enumerating, before the Congress met, the excursions which might be made in Portugal I briefly explained that here the monks had cultivated the plants brought over by a wall ten feet high and, as already stated, a Bull issued by Urban VIII. in 1643 punished with excommunication anyone who injured the trees. As the wall preserving this forest is two and a half miles long there is to be found here a large plantation of gigantic trees, for many of them are several centuries old. That a considerable proportion of the trees are cedar, pine, and eucalyptus contributes to render the air pure and balsamic.

As already explained, when the monastical orders were abolished and this estate became national property a palace was built in the Emmanuel or Gothico-Manoelino style as a

wedding present to H.M. Carlos I. and it is this palace which now serves as a hotel for tourists and residents. Certainly it is an imposing structure and the beautiful ornamental stone carving work is very charming. A broad gallery or cloister with pillars and arches of carved white-stone goes round three of the sides of the main building. It is therefore easy to find a place in the open air where there are shade and shelter from rain or wind. Thus open air can be enjoyed even under this beautiful stone verandah or gallery on those rare occasions when bad weather prevails. The hotel is situated on the highest hill of the

FIG. 1.

The monumental palace and hotel, showing the stone carving and the sheltered gallery round the building.

neighbourhood and half an hour's climb below its summit. There are level walks skirting round the hill on either side, while there are many carriage roads and bridle paths going up or down in all directions. At every opening among the trees a fresh panorama reveals itself. It is a land of enchantment. My first impression was that I had never been to a place more eminently fitted for doing nothing whatsoever. To sit still, to breathe the fragrant air, to gaze with admiration on the scene was enough, and more than enough, for it is wonderful how soon the new-comers are overcome with the desire to sleep. This is indeed a restful place. There is no town, no traffic near at hand, nothing to disturb the quietude or to pollute the atmosphere. From the summit of the hill, immediately behind this palace and hotel, a view can be obtained that extends from the sea on the west to the first mountains of Spain which appear dimly on the horizon of the east. To the south the ancient university town of Coimbra and the Mondego valley are easily discernible, and to the west and north are long chains of pine-covered mountains. These forests keep the air delightfully cool in summer while they break the force of the cold winds in winter. For the Portuguese Busaco is a summer resort, while the British go there to escape the rigour of winter. The wonder is the extent of the panoramic views. It is impossible to count the mountains, they are like the waves of the ocean. It is altogether different from Switzerland and more like the lower Balkan ranges in Servia. The curious thing is that, though there are so many mountains, there is no sense of being shut in, but, on the contrary, that of a far-reaching expanse. It is near enough to the sea to feel some effects of the saline breezes, high enough to be always refreshed by a cool breeze, and the isolation and vegetation insure the purity and the balsamic quality of the air.

There are also numerous springs in the neighbourhood, mineral and sulphur springs, and one that professes to rival the waters of Contrexéville. Even on the estate itself there are six different springs containing more or less salts of soda which might be used to assist digestion. But, of course, before pronouncing any definite opinion on such a matter elaborate researches must be made. For the moment all that can be said is that there is reason to believe that many medicinal agencies will probably be discovered when the place is better known and developed. At the small town of Luzo is the nearest railway station, from which a short drive through a majestic forest brings one to

Busaco, while from the Busaco hotel a motor-car or an omnibus takes visitors down to the baths at Luzo. There is a bathing establishment; it is a modest structure but it contains all that is necessary. These are sulphur baths but close by there is a spring that gives forth a great quantity of carbonic acid. A small pond surrounded by a masonry wall has been made in which the people dip their buckets and jugs at the great risk of contaminating the water. It is called the fountain of San João and a little votive chapel to the saint is erected just above the spring. It was once proposed to remove the chapel, to cover over the spring, and to endeavour to bottle some of the water before all the gas which it contains escapes. The pious inhabitants were, however, greatly scandalised. They qualified such measures as a desecration and maintained that if this was done the saint would certainly prevent the water coming any more. So, for the time, this water is lost. The upper reaches close to the chapel are contaminated by the careless way in which pitchers and pails are thrown in and the lower reaches are used by the people to wash their dirty linen. Yet, it is obvious to the naked eye that the water is rich with carbonic acid and would probably provide a very agreeable and wholesome table water.

FIG. 2.

Garden in front of the hotel showing the semi-tropical vegetation.

Ouria, where the waters are supposed to rival those of Contrexéville, is somewhat farther off but nevertheless can with a motor-car be reached easily from Busaco where the accommodation and the surroundings are much more suitable for residence. Undoubtedly many people would go to Busaco if the place was better known and if the persons interested felt a sufficient security of tenure to make efforts to attract visitors. This brings me to the question raised as to whether the Portuguese themselves will aid or will impede the development of their own country. As for the people I have heard nothing but good of them, at least round about Busaco. Labour is cheap, indeed much too cheap, for it is impossible to ask people who earn so little to carry out in their homes the sanitary reforms and measures that should be introduced. The women labourers often get only about 6*d.* per day and the men twice that amount, though it is acknowledged that the women frequently do quite as much work as the men. It is true that they do not depend on such low wages for their existence, for they mostly possess some land and only hire themselves out when they have no more work to do on their own small holdings. What, however, must be the condition of those who have no property of their own to fall back upon, though fortunately this is the exception and not the rule. These people are honest, hardworking, and absolutely trustworthy. At Busaco everything is left open. No one ever thinks of locking a door. Once a year there is a great pilgrimage. Some 10 000 people come to Busaco and religious services are held in the woods and at the shrines of the ancient monks. When this is terminated there is a great feast. There are, of course, much drinking and some drunkenness, though not anything like what would result if a similar crowd went out for a picnic in England. There are a great deal of noise and some quarrelling, but knives are never used and nothing has ever been stolen.

Though the mass of the Portuguese are evidently a simple-minded trustworthy people the same cannot be said of the officials in the larger towns. One fatal circumstance is that they are not paid enough and must make money in some way or other over and above their salaries. Hence the business man who comes to Portugal is likely to be harassed and exposed to many extortions. This sort of pin-prick policy is likely to render life burdensome and to discourage enterprise. Thus, for instance, at Busaco, when the palace was given over, though but in a vague, undefined manner, as a hotel the first condition was that the State only should build. Now the granting of a permanent lease is conditional on a certain amount of building being done, but of course the tenant wants security of tenure before sinking large sums in building. At first the palace was not occupied at all. The building which is now the post-office served as a hotel. Then the Minister of War came down and said that if the palace was furnished there would be plenty of people wishing for rooms because the autumn manoeuvres were to take place in the neighbourhood and thus the palace was occupied for the first time as a hotel. Afterwards, however, both the local and Lisbon authorities ordered all the furniture to be taken out. The protest that this would injure the furniture was unavailing, so the palace was dismantled. Subsequently, many of the people who had been there wanted to return but it was impossible to receive them. If I am not mistaken, the King himself finally took the matter in hand and permission was given to put the furniture back. Nevertheless, to this day there is no permanent agreement or lease.

This monumental hotel, which is much more of a monument than a hotel, contains 46 rooms of which only 22 are available for visitors, the others being mostly servants' rooms, and there are 20 rooms in the annexe. Palatial drawing rooms, state halls, and stairs are very grand and pleasing in their way but they bring in no rent. It is the bedrooms that pay and, of course, a palace is not built on the business principles of a hotel. An annexe with from 50 to 100 bedrooms is needed and the offer is made to build this and to incur all the expense necessary to make a financial success of the whole affair in exchange for a 35 years' lease. After that time the whole of the property, the goodwill, and the business created is to revert to the State. Instead of this the State wants to put a sort of functionary, a forest ranger, to supervise the whole enterprise. There is no sort of evidence to show that such a functionary would possess the smallest technical knowledge of the hotel and health resort business, yet nothing whatsoever is to be done without consulting and obtaining the approval of this functionary. If a tile is blown off the roof it cannot be replaced without his consent and he may at will cause any of the servants to be dismissed. Then any and all visitors must be allowed to inspect the hotel as if it was a sort of museum. Of course, any decent person wishing to go round is shown whatever is of interest, but under the proposed agreement a person might behave uproariously or pretend to be drunk and on being refused admittance and bearing witness to that effect the Government would have the right to tear up the contract. Many other clauses place this business enterprise at the mercy of the caprice of a local functionary.

This is all a matter of more than local importance. Even under the present unstable state of affairs there have been during the last 12 months about 3000 Portuguese and 800 foreign visitors to Busaco. This is not much but it is enough to make short-sighted, inexperienced persons imagine that already fortunes are being realised and the tendency seems to be that of killing the goose that may lay the golden eggs. Yet the first step towards developing health and holiday resorts in Portugal is to give business facilities. The Portuguese know little or nothing about such business. They should, like the Japanese, welcome those who can give them the much-needed and useful object lessons, but to judge from what is happening at Busaco this is not the case. Busaco, I believe, is the nearest approach to a success in Portugal. If this is allowed to fall through harassing and unbusinesslike restrictions the hope of success elsewhere will be reduced to a minimum. On the other hand, there is much to be done elsewhere—watering stations, sea-bathing stations, sheltered winter resorts, and high altitudes for out-of-door treatment amid snow and sunshine as at Davos Platz are all available,

if men with enterprise and with the needed technical knowledge are encouraged. As for the money necessary, it can be had for the asking, if those who are to manage are persons of experience and are known to possess the special knowledge on which success depends.

So great are the attractions of Busaco that the Queen has built herself a villa close to the Hotel Palace and the King goes there also every year. Naturally the best society of Portugal follows their example; while in the early spring and late autumn there is an increasing influx of foreigners. But the accommodation is barely sufficient. Portions of the palace are not yet completed. The artist who was painting the stairs was called away to finish the new medical schools at Lisbon in time for the International Congress of Medicine and thus the scaffolding remains and has remained for many months on the stairs at Busaco. Such delays on Government premises may not matter much, but slow building operations will not help to fill a hotel. These incidents

FIG. 3.

The Queen of Portugal's villa and the chimes of the old Carmelite Monastery, with cedar trees that are some centuries old in the background.

suffice to show the lack of business knowledge and activity. If the pleasure and health resorts of Portugal are to reap the advantages which the recent International Congress of Medicine might help to bring them they must be placed under the supreme control of persons who possess the special and necessary business capacity and experience.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Mills and Motherhood.

It may be remembered that a committee of the Blackburn branch of the Christian Social Union was formed some little time since to investigate the influence that the employment of married women in mills has on infant mortality. Two medical men, Dr. M. Bannister and Dr. P. Prebble, and several ladies, including the matron of the infirmary and the matron of the District Nurses' Home, served on the committee. The report of the committee has now been issued. The prohibition of the employing of women in mills, even if desirable, the committee considers impossible owing to economic obstacles and its restriction would be very difficult. To diminish the economic difficulties the committee suggests the establishment in mills of maternity funds from which payments might be made to women immediately before and after confinement. It does not seem to think that mill work necessarily unfits women for domestic life but that more attention should be given in the schools to teaching girls how to look after a house and children, and that girls over 18 years of age, too, should have opportunities of learning these things. It considers the high infant mortality due mainly to improper feeding and not to the mothers working in the mills. All the attention recently paid to the subject has, of course, led to a good deal of newspaper correspondence and in contrast to the somewhat lenient

view of the committee on the effects of mill life on married women the picture drawn by a mill-worker of over 30 years puts the case in a more unfavourable light. The woman worker hurries to the mill, where she sits or stands—as the case may be—before her frame for the whole of the working hours. "Her meals for the most part consist of tea and bread-and-butter, with possibly at dinner time a few 'chips' from the nearest shop." In the early morning there is the worry of getting the youngest child out of bed to be carried, wrapped in a shawl, to a neighbour's house. Then in the half hour allowed for breakfast the children have to be got ready for school after a hurried meal of tea and a "butty," and the mother has to rush off to the mill, often "eating her remnant of breakfast as she goes." The consequences of this course of life are that the mother and children are ailing and often under medical supervision. The faces of the women soon acquire a worn look, their lives are "one constant round of petty, nagging cares," they "grow pale and haggard-looking before their time," and clearly they are not those whose healthy vigour fits them to be the mothers of a stalwart race. Anyone who knows the Lancashire mill-hands will know that this picture is not over-coloured. It would be absurd to expect a vigorous race under the conditions of town and factory life at present obtaining. Something may, perhaps, be done to dispel the almost incredible ignorance of how to live which prevails among the mill-hands. So far the compulsory attendance of the children at the elementary schools has done next to nothing to give them practical help in leading healthy lives. Ladies' health societies and such like agencies are good but they cannot overtake the work. It seems, however, as if we were becoming more aware of the deficiencies of our elementary education and therefore the future may be looked to with some hope of improvement. In the new code just issued more attention is paid than of old to the physical education of the child.

Proposed Extension of the Water-supply.

The Manchester water committee proposes not only to lay a third pipe from Thirlmere but to extend in some degree the reservoir works at Longendale which before Thirlmere was drawn upon were the main source of supply for Manchester. The construction of these works began in 1848 and the water was first delivered to the city in 1851. There are now five reservoirs in the main valley and two have been constructed on the Arnfield and Hollingworth brooks and there are reservoirs at Audenshaw where, however, there is a loss of storage through colliery workings. Exclusive of compensation water the average quantity obtained per day from Longendale in the four years 1887-1890, four years with less than the average rainfall, was 20,434,865 gallons, but Mr. Hill, the engineer, does not think that Longendale can in dry seasons be safely reckoned on to supply more than 20,000,000 gallons. This, with the Thirlmere supply from two pipes of 20,000,000, will probably meet the requirements for four or five years. In 1905 the total daily consumption of water was at the rate of 36,219,578 gallons and Mr. Hill says that no substantial increase in the supply can be obtained from any source but Thirlmere and he thinks that the third pipe should be ready by about 1910.

Ophthalmia at the Salford Union Hospital.

It was proposed at a meeting of the guardians on June 29th that an eye specialist should be engaged to treat the eyes of the children in the "eye sheds" at the hospital. The proposition was enforced by the statement that a boy whose case had been pronounced incurable was sent to the Royal Eye Hospital from the sheds and within a month he was cured; also that there were many cases of ophthalmia that had been in the sheds two years. It seems that the ophthalmia cases had been reduced from 60 to 18, and as one of the guardians stated, "except for new cases they could wipe them out altogether." He estimated the cost of a specialist at nearly £200 a year, but the mover of the proposition said that the medical officers at the hospital had each 400 patients in their care and that the cost of a specialist would be only £50 a year. Although a strong case was made out for this special help the motion was defeated.

Charitable Bequests.

The late Mr. James Holden of Rochdale left estate of over £120,000 for charitable purposes, and the trustees have made the following grants. The Manchester Royal Infirmary is to

receive £5000, the Northern Hospital for Women and Children £2000, Blackpool Victoria Hospital £1000, and Lytham Cottage Hospital £1000.

July 3rd.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Water supply of Swansea.

THE Swansea waterworks in the Cray Valley, Brecknockshire, are now completed. The reservoir has a storage capacity of 1,000,000,000 gallons. The waterworks were begun in 1894 under contract, but owing to disputes and litigation the corporation bought out the contractors at a cost of £26,000 and finished the work itself. The expenditure on the undertaking, including land, has exceeded £500,000.

Honorary Dental Surgeons and the Carmarthen Education Committee.

At the last monthly meeting of the Carmarthen borough education committee it was unanimously resolved to invite local dental surgeons to act as honorary dentists to the education authority, with a view to the making of periodical inspections of the teeth of children attending the elementary schools and to the giving of occasional instruction to the children and their parents on the preservation of their teeth.

Hereford City and County Asylum.

One of the most striking features in the thirty-fourth annual report of the committee of visitors of the Hereford county and city asylum is the statement that there is no special accommodation for isolating cases of infectious disease. It seems inconceivable that those who are responsible for the management of an institution which during 1905 had a daily average of 536 patients under treatment should have neglected to make adequate provision for this class of case. This neglect can hardly be said to be due to ignorance, for the medical superintendent (Mr. C. S. Morrison) and the Commissioners in Lunacy have again and again pointed out the need for such accommodation. In commenting upon an outbreak of measles, which lasted from February till May of last year and in which 34 patients and attendants were attacked, the Commissioners point out that it would probably not have attained such proportions had it been possible to secure the prompt isolation of the earliest cases. In his contribution to the report the medical superintendent comments upon the large number of patients who are admitted above the age of 30 or 35 years and in whom there is distinct evidence of cardio-vascular disease. Though there may be some difference of opinion as to whether the disproportionate number of persons who become prematurely senile is to be attributed to hereditary causes or to improper feeding when young, Mr. Morrison considers it is certain that alcohol is a large contributory factor. The Herefordshire labourer will have his full ration of beer or of cider even if his supply of meat is curtailed. It is, however, striking that while Herefordshire has the largest ratio to population of pauperism and confirmed insanity among the English and Welsh counties, yet from the standpoint of police returns it is an exceptionally sober county.

Brentry Inebriates' Home.

When the home for inebriates was established at Brentry, near Bristol, it was the intention of the founders that it should be a curative rather than a penal institution. The class of persons sent there in the early years of its existence were those whose only offence was drunkenness and who, if allowed their full liberty, were unable to withstand the temptation to drink. Lately, however, habitual criminals have been sent to the home until it has been possible for a member of the managing committee to report to the Gloucestershire standing joint committee that there are now in the institution as fine specimens of the criminal class as are to be found outside the walls of a criminal prison. The result of bringing together this class of person in a prison which is not really a prison must have been foreseen, so that it is not surprising to find that on a certain Sunday in June a serious outbreak occurred, when three of the attendants were maltreated and property was damaged. Assistance was fortunately obtained from Gloucester and from Bristol and the

ringleaders have since been sentenced to various terms of hard labour. After this experience it is to be hoped that the managers, or those who are directly responsible for sending persons to the home, will endeavour to carry out more accurately the very laudable intentions of the founders of the institution.

The Incorporated Society of Medical Officers of Health.

The annual provincial meeting of the Incorporated Society of Medical Officers of Health will be held on Saturday, July 14th, at Bath, when Mr. C. S. Loch, the secretary of the Charity Organisation Society, will open a discussion upon the Relation of Sanitary Authorities to Charitable Organisations. In the evening there will be a public dinner and a reception in the Roman Baths by the President and members of the West of England and South Wales branch of the society.

The Adulteration of Butter.

By instruction of the Board of Agriculture the proprietor of the Bridgwater Creamery Company has been prosecuted before the Bristol magistrates for selling margarine to which a false description was applied. Evidence showed that by an ingenious system "nutrine" or "lardine" was worked up with butter and on an order being sent from a Bristol grocer for butter an article was received which on analysis was shown to contain 20 per cent. of this ingredient. The invoice bore the statement, "guaranteed pure and unadulterated within the meaning of the Food and Drugs Act." It was stated that the profits realised appeared very great. The bench of magistrates characterised the case as probably the worst that had ever been heard before them and on the application of the counsel for the Board of Agriculture they inflicted the heaviest penalty in their power—viz., £20 fine in each of the two cases for which the defendant was prosecuted and 50 guineas costs.

July 3rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Results of the Scottish Medical Preliminary Examinations.

THE Joint Board of Examiners of the Scottish Universities has issued the statistics of the preliminary examination at the entrance to the medical curriculum. At the University of St. Andrews six candidates entered for the four requisite subjects; one failed in all the subjects and two passed in all the subjects; at Glasgow 47 entered, seven failed in all, and 17 passed in all the subjects; at Aberdeen 16 entered, two failed in all, and four passed in all; and at Edinburgh 76 entered, ten failed in all the subjects and 28 passed in all the subjects.

Professor McKendrick's Valedictory Address.

Professor J. G. McKendrick, who is retiring from the chair of physiology in the University of Glasgow, delivered his valedictory address to the students last week at the close of the summer session. In the course of his address Professor McKendrick dealt with the progress of the science of physiology during the last 30 years, which he defined as the application of the methods of histology, chemistry, and physical science generally to the elucidation of the phenomena of life. So far as histology was concerned immense progress had been made. The microscope had been so improved that of physical instruments it was perhaps the one which most nearly approached perfection. The methods of histological research had also become more thorough and scientific and it was doubtful if much more progress in the direction of histology could be made. As to the experimental methods, those that were possible with living tissues from recently killed animals had been well worked out. The phenomena of animal electricity had been investigated with remarkable success. Until recently there seemed little hope of further progress, but within the last few years the phenomena of ionisation appeared to offer a new field for investigation. In dealing with the question of vivisection, Professor McKendrick, who disclaimed desire to discuss the subject controversially, said that he found it difficult to imagine how those who denied its use altogether in physiological science could fail to see what remarkable progress had been made in our knowledge of the digestive processes by such methods. While saying this he urged

that it was not necessary to repeat the experiments of previous observers except possibly at the beginning of a new line of research. As regards the education of students of medicine, Professor McKendrick was of opinion that too much time and energy had been expended on difficult experimental work, on the physiology of nerve and muscle, and on relatively unimportant matters in electro-physiology. In the future the experimental course should be much broadened, so as to include simple experiments on the hydraulics of the circulation, on respiration, on the physical properties of the blood, on the phenomena of the senses, and on processes of digestion. During the past 30 years the two departments of physiological science in which there had been, in his judgment, the most marked progress were the knowledge of the nerve paths to the central nervous system and the subject of internal secretions. As regards the future there was no doubt that it was in the direction of physiological chemistry that they would have to look for the greatest progress during the next few decades. At the conclusion of his address Professor McKendrick bade farewell to his students.

Glasgow Post-office.

Great interest is being taken by the members of the medical profession in Glasgow in the appointment of medical officers to the Post-office. It has been arranged that the appointment is not now to go to one man and the city has been divided into six districts, to each of which one medical man will be appointed. Each of the medical men appointed must be between 30 and 60 years of age, must reside in his district, and will be allowed to carry on private practice. It is proposed to fix an age-limit for the tenure of the appointment but this has still to be determined.

Inspection of Meat in Glasgow.

At a meeting of the Glasgow corporation health committee's subcommittee on the inspection of meat and fish there was considered a request by the Glasgow United Fleshers' Society to be allowed to receive the best parts of unmarketable carcasses in order that they might be sterilised in premises to be provided for the purpose and thereafter sold for consumption as human food, as is done on the continent. At the same meeting, in dealing with the question of the importation of boneless meat and offal and the possibility of provision being made for the proper inspection of such commodities, the subcommittee recommended that representations should be made to the Government to take steps for seeing that such meat is properly inspected at the places of slaughter or otherwise to have an embargo placed upon its importation.

Scottish Dentists.

The members of the Scottish branch of the British Dental Association held their annual meeting at Moffat on June 22nd, and on the 23rd the party had an excursion to St. Mary's Loch. On the 22nd, following the business part of the proceedings, a dinner was held in the Buccleuch Arms Hotel, at which there was a company of about 30. The President of the branch, Mr. D. Cumming, L.D.S., of Falkirk, presided, and among the guests present was Provost Knight of Moffat.

University of Aberdeen Anatomical and Anthropological Society.

At a meeting on June 30th, Professor R. W. Reid presiding, anatomical variations were described by Mr. G. S. Melvin and the President. The treasurer's report was read and the following office-bearers for the coming year were elected:—President: Professor R. W. Reid. Vice-Presidents: Dr. Alexander Low, Dr. W. A. H. McKerrow, and Mr. James Watt, M.A. Secretary: Mr. A. G. Stewart, M.A. Recording secretary: Mr. J. D. Fiddes, M.A. Treasurer: Mr. G. S. Melvin.

Extension of Marischal College.

The adamant pavement in front of the new buildings at Marischal College having now been laid the wooden hoarding—which was erected when operations in connexion with the building of the front block were commenced—has been removed. It is expected that a start will be made soon with the laying of the wooden paving in Broad-street, between Queen-street and Upper Kirkgate.

The Cost of Maintenance at Kingsseat Asylum.

A meeting of the asylum committee of the Aberdeen city district lunacy board was held on June 26th, Mr. William

Giles presiding in the absence of Mr. James Cheyne, the convener. From a statement submitted of the expenditure on the maintenance of the asylum for the year ending May 15th last it was shown that there was a balance to the credit of the maintenance account of £875 9s. 5d., and a balance to the credit of the providing account of £282 3s. 5d. The maintenance cost of patients per head per annum was £25 2s. The estimated number of patients for the year ending May 15th, 1907, is 428 and the estimated maintenance account for the year is £10,700, being at the rate of £25 per patient per annum. The amount to be raised by assessment this year will be £1011 less than the amount assessed for last year, this being equal to about three-eighths of a penny per £ less than last year's rate of assessment.

The summer graduation ceremony at Aberdeen has been provisionally fixed for Wednesday, July 25th.
July 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Consumption in Ireland.

THE Local Government Board of Ireland has issued to the clerk of each urban and rural council in Ireland a circular on the above subject giving useful instructions for dealing with this important disease. It points out that the death-rate for the years 1902, 1903, and 1904 shows an upward tendency in Ireland, the figures being as follows:—

Year.	Total number of deaths from all forms of tuberculosis.	Number of deaths from pulmonary tuberculosis (consumption).
1902	11,837	9400
1903	12,180	9559
1904	12,694	9833

In 1904 (the latest available returns) the figures 9833 represent a death-rate of 2·9 per 1000, which rate has only been reached on four previous occasions. In England the death-rate from tuberculosis has gradually fallen, until in 1904 it has reached 1·23, or less than one-half of the death-rate in Ireland. It is, perhaps, a pity that this circular of the Irish Local Government Board did not follow the lead of the one issued by the Scotch Local Government Board and regard consumption as an infectious disease, to be dealt with by such measures as are applicable to infectious diseases; but it is, at any rate, satisfactory to see that official effort is being made to stem what is rapidly becoming a national calamity. Mr. R. A. Brown, secretary of the Ulster branch of the National Association for the Prevention of Consumption in Ireland, has sent to each Irish Member of Parliament a copy of a pamphlet pointing out the deplorable position which Ireland occupies in reference to consumption, seeing that in their country nearly 13,000 deaths annually are due to the malady. Mr. Bryce, the Chief Secretary for Ireland, has promised that his department will do its best.

School of Physio, Trinity College.

Sir John Banks, K.C.B., physician-in-ordinary to the King in Ireland, Regius professor of physic, Trinity College, Dublin, has recently endowed a medal, to be called "The Banks medal," and a money prize, to be awarded to the two foremost candidates at the examination held every second year for the medical travelling prize in Trinity College, Dublin.

Honour for Sir Christopher Nixon.

Sir Christopher John Nixon, who was knighted in 1895 and has now been raised to the dignity of a baronet, is a son of Mr. C. W. Nixon of Dublin and was born in that city in 1849. He took the diploma of L.R.C.S. Irel. in 1868, was elected a Fellow of the College of Physicians of Ireland in 1876, graduated as M.B. at the University of Dublin in 1878, and in 1885 received the degree of M.D. from the Royal University of Ireland. In 1872 he married Mary Anna, daughter of Mr. Dominick Blake of Galway. Sir Christopher Nixon's position as a leading member

of the medical profession in Dublin naturally implies the holding of distinguished appointments. He is an ex-President of the Royal College of Physicians of Ireland and is a member of the General Medical Council, in which he has represented the Royal University of Ireland since 1897. He is professor of medicine at the Catholic University and senior physician to the Mater Misericordiæ Hospital, Dublin. He was the first President of the Royal Veterinary College of Ireland, an institution in the founding of which he took an active interest. He is the author of a "Hand-book of Hospital Practice and Physical Diagnosis," published in 1888, and of various papers and memoirs on professional subjects.

Apothecaries' Hall of Ireland.

On June 29th in the examination room of the Apothecaries' Hall, Mary-street, Dublin, the freedom of the Worshipful Company of Apothecaries was conferred on Sir Christopher J. Nixon, Bart., and on Dr. Denis Joseph Coffey, lecturer on physiology, histology, and elementary biology in the Catholic University Medical School, Cecilia-street, Dublin, and examiner in physiology of the Royal University of Ireland. Mr. G. R. S. Stritch, the deputy governor of the Company, in introducing Sir Christopher Nixon, said that the baronetcy just conferred on him was an honour pleasing to its recipient and delightful not only to the medical profession in Ireland but to the large circle of his patients. The magnitude of the honour could only be properly appreciated when it was considered that among the thousands of men whose names appeared on the Medical Register there were at present only 14 baronets. It was well merited not only on account of Sir Christopher Nixon's conspicuous professional attainments but also for his unflinching courteousness, affability, and kindness of heart. In introducing Dr. Coffey, Mr. Stritch said that his integrity of character and purity of purpose had caused him to be singled out from amongst many others as a gentleman worthy of filling the responsible position of a member of the Royal Commission recently appointed in connexion with the University of Dublin.

Royal College of Surgeons in Ireland.

The preliminary announcement relative to the Barker anatomical prize to be awarded in 1907 states that this prize of £21 is open to any student whose name is on the anatomical class list of any school in the United Kingdom. The preparations entered must be placed in charge of the curator of the Royal College of Surgeons in Ireland on or before April 30th, 1907. The prize is offered for a dissection showing the viscera in relation with the abdominal surface of the diaphragm. The relations of the common bile-duct, which should be seen opened up along its entire length, are to be fully retained. The preparation must be marked with a fictitious signature and accompanied by a sealed envelope bearing outside the same signature and containing inside it the name of the competitor.

Scheme of Sewerage and Water-supply for Newtownards.

The Newtownards urban district council on June 26th had the preamble of its Bill for a proper scheme of sewerage and water-supply approved by the Police and Sanitary Committee of the House of Commons. Newtownards is a prosperous Ulster town about eight miles from Belfast, situated at the northern extremity of Strangford Lough, and it has neither a proper sewerage works nor a water-supply, so that it is hoped that these defects will now be remedied.

Queen's College, Belfast.

On June 30th Sir Donald Currie visited Queen's College, Belfast, where he was presented with addresses from the president and council and from the students in recognition of his munificent gift of £20,000 to the better equipment fund of the College. In responding he made an interesting speech, in the course of which he offered to give one-fourth of the £5000 required for the provision of suitable athletic grounds if the students would raise the remainder in a year, a challenge which was promptly accepted. It is contemplated to raise the money by means of a bazaar.

The Medical Officer of Health of Belfast.

At a meeting of the city council of Belfast held on July 2nd the members confirmed the resolution passed previously by the council in committee that the salary of the new medical officer of health should be £600. The Lord Mayor pointed out that it would be well to wait until

the Local Government Board had given its opinion on the matter as he did not expect that it would confirm the resolution. He appears to have good grounds for his opinion. The view of the reform party in Belfast is that the Local Government Board should insist on a larger salary being paid, and should demand that candidates for the office should have had special training in public health otherwise Belfast will be placed in a ridiculous position. The citizens are at present in this unfortunate plight that they must look to the Local Government Board to protect them against their own corporation which is apparently blind to the seriousness of the situation. A city of 360,000 inhabitants requires as its chief medical adviser a man of the very highest attainments, qualifications, and special experience, while a salary of £600 may limit the number of candidates in such a way that no one having the necessary attributes may apply. It is rumoured that some of the corporation who believe that £600 are enough have a candidate of their own for the post. The death-rate of Belfast from all causes for the four weeks ending June 16th was 20·8 per 1000, while in the corresponding four weeks of last year the death-rate was 18·5 per 1000. Facts like these appeal to the popular imagination and it is not surprising that they do so.

The Serum Treatment of Tuberculosis.

At a meeting of the Academy of Sciences held on June 25th M. Lannelongue read a paper giving an account of some investigations which he had made in association with Dr. Achard and Dr. Gaillard on the serum treatment of tuberculosis. Questions relative to vaccination methods and the use of antitoxins have been proposed and followed up for some time with the greatest activity. For the last seven years the experimenters have been trying on guinea-pigs a toxin extracted from the bacillus occurring in the human subject. Guinea-pigs reacted to tuberculous infection almost like human beings and they were very receptive for the human bacillus. Pulmonary tuberculosis was artificially produced in them and they were afterwards submitted to therapeutic processes; all the results of observation led to the belief that if guinea-pigs recovered after suffering from pulmonary tuberculosis human beings might recover also. Professor Lannelongue described two experiments in which a large number of animals were used. In the first experiment four groups of equal weight, each consisting of 30 guinea-pigs, were inoculated in the lungs with the same dose of a virulent culture. The first group was taken as a control; the second was treated with the serum of normal asses' blood; the third was treated with the serum of asses' blood, presumed to be antituberculous; and the fourth was treated with a prophylactic injection of this latter serum previously to the tuberculous inoculation. The final result was that 372 days after the inoculations the mortality in the various groups was 90 per cent. for the control group, 87 per cent. for the group injected with normal serum, 40 per cent. for the group injected with antituberculous serum, and 64 per cent. for the group injected prophylactically. In the second experiment the investigators endeavoured to immunise a horse and used its serum. The guinea-pigs were divided into two groups of 50 each, one of these being taken as the control and the other being treated with the serum. Both groups were inoculated in the lungs on the same day. After 16½ months the mortality was 78 per cent. in the control group and only 42 per cent. in the group treated with serum; while after 20½ months the mortality was 98 per cent. in the control group and 60 per cent. in the group treated with serum. Necropsies of all the animals were made; they showed that generalised pulmonary lesions predominated in the control animals, whereas the lesions in those which had been injected with serum were either circumscribed or very little advanced. Among the last-mentioned animals, some had lesions hardly visible to the naked eye, some showed cicatrices of recovery, and others did not show any lesion at all. M. Lannelongue and those who worked with him thought that the time had come for the systematic treatment of patients with the serum of asses' blood, preferably with that of immunised animals; some

observations which have been already made on patients showed that the treatment was well tolerated and did not cause any rise of temperature.

Sudden Congestion or Acute Hæmatoma of the Uvula.

At a meeting of the Academy of Medicine held on June 12th M. Fabre (of Commeny) said that the uvula was sometimes the seat of a sudden congestion or local apoplexy which caused a tickling sensation as if a foreign body were in the back of the throat; this was soon followed in the first place by an urgent desire to swallow or cough up the cause of the annoyance and in the second place by violent coughing, retching, or vomiting. These symptoms were caused by a hæmatoma of the uvula, presenting a globular form like a cherry attached to the velum palati. M. Fabre has observed this condition five times altogether—three times in men and twice in women. In two cases there was no apparent cause for it and in one it was due to scratching of the part by a hastily swallowed crust of bread. The treatment consisted in puncture of the swelling, followed by astringent gargles made with alum, tannin, or rhatany.

An Indigenous Case of Madura Foot.

At a meeting of the Academy of Medicine held on June 19th M. Reynier reported the occurrence of a case of Madura foot in a man who had never been out of France. He said that this was the first case of the kind in France and the second in Europe. Madura foot was a disease of hot countries where the inhabitants walked barefoot. The lesion (mycotoma) consisted of a swelling due to the presence of parasites and containing granular particles of various colours, principally white. The patient under the care of M. Reynier was a man, 51 years of age, an indoor servant, who had never been out of Paris. In the year 1892 he noticed on his foot a blister which discharged a little serous fluid. M. Danlos saw the case and considered it to be syphilitic. Rather more than a year afterwards the place became painful. In 1893, when the man was admitted as a hospital patient under the care of M. Reynier, there was a large blister with numerous fistulæ, but the articulations of the foot were unaffected. The lesion was suggestive of actinomycosis, but treatment gave no result and M. Reynier amputated in the lower third of the leg. The bones were quite sound, whereas in actinomycosis they were usually affected. In the sclerosed tissue there were nodules containing each a granule surrounded with pus. The granules were rolled up like the excrement of earthworms and consisted of a felted cord of mycelial tubes with an enlarged extremity.

Surgical Treatment of Lupus of the Face.

At a meeting of the French Society of Dermatology and Syphilography held on June 7th M. Morestin showed two patients in whom lupus of the face had been treated by excision and subsequent autoplasty. In one of the cases the disease extended over the greater portion of the left cheek and the wound was filled by a flap taken from the suprahyoid and subhyoid region. This flap united perfectly but after some time a doubtful spot appeared on its edge; this was removed under cocaine and the result has been good up to now. In the second case the disease was less extensive and was situated on the right cheek; the effect of the operation as regards appearance was satisfactory.

Treatment of Late Diphtheritic Paralysis by Injections of Antitoxic Serum.

At a meeting of the Société Médicale des Hôpitaux held on June 13th M. Comby described the case of a girl, aged four years, who suffered from diphtheritic paralysis of all four limbs and of the pharynx, coming on about a month after recovery from an attack of diphtheria in the throat. After four injections of antitoxic serum repeated at intervals of three days she made a complete and very quick recovery. M. Barbier said that it was not uncommon for patients, especially adults, some days or weeks after an attack of diphtheria affecting the throat to die suddenly or after a short illness from bulbar paralysis. The patients most liable to suffer in this way were either those whose treatment was undertaken too late or was otherwise unsatisfactory or those who were attacked with the severe pseudo-membranous form of diphtheria. The symptoms which preceded bulbar paralysis were mental depression, anxiety, prostration, and tachycardia. The only treatment consisted in the immediate giving of a few series of injections of antitoxic serum.

Iodide of Potassium in the Treatment of Dry Pleurisy.

M. Jacquet and M. Luzoir have observed three remarkable instances of the resolving action of iodide of potassium in dry pleurisy. In one of these cases the friction sounds were of a quite remarkable intensity and perceptible at a considerable distance from the thorax, but these sounds disappeared in a few days under the influence of iodide of potassium solely. In the patient who was shown the inflammation was of exactly three weeks' duration, and there were intense friction sounds extending over a great part of the right pleura. The iodide was administered on May 26th in a dose of one gramme and on the 28th the improvement already referred to was evident. From May 28th to June 2nd three grammes were taken and there was a decline of the friction sounds day by day, terminating on June 3rd in a total disappearance of them which has been maintained ever since. This mode of treatment was not entirely new, but striking instances of this kind were so little known that the cases deserved attention. M. Jacquet and M. Luzoir communicated their paper at a meeting of the Société Médicale des Hôpitaux held on June 22nd.

Vaccination at Tongking.

Near Hanoi there is an institution for the production of vaccine lymph. It was founded in 1904 and the results which it yielded during 1905 were extremely satisfactory. The output of vaccine lymph rose to 632,785 portions (*doses*), of which 480,929 portions were used in Tongking, Annam, and the neighbouring countries. The magnitude of the production has not interfered with the quality of the lymph, for 95 per cent. of the vaccinations were successful. The principal part of this lymph was supplied to medical men who were public vaccinators. At the commencement of 1905 this institute supplied only the public vaccinators in Tongking, but its field of action has by degrees become larger and the public vaccinators of Annam are beginning to use its products concurrently with those of the institute at Saigon. The natives are not showing any antipathy to vaccination; owing to the success which has been obtained they recognise its good effects in connexion with small-pox and they do not hesitate to bring their children to the public vaccinators.

July 3rd.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Maternity Hospitals for the Provinces.

THE Turkish newspaper *Ikdam*, which is published in Stamboul, has announced that the Ottoman Government has decided to establish maternity hospitals in the chief provincial towns. Some will, it is supposed, be located in the pavilions of the female section of the already existing infirmaries in these towns, while some will be constructed *de novo*. These establishments will have modest proportions to begin with, but it is intended to increase and to develop them little by little and thus to meet in future all the necessary requirements of such institutions. All the women *en couche*, especially those of the poorer classes, will receive there careful treatment at the hands of medical men and qualified midwives. Should this decision of the Ottoman Government take a definite practical issue it will prove to be a great boon to females in the provinces, for in provincial Turkey pregnant women are exposed to many dangers owing to the practices indulged in by a formidable host of unqualified, unscrupulous, extremely ignorant and superstitious *sages-femmes*. These latter hold almost an unlimited sway in the provinces and indeed in the suburban districts of the capital itself. I have under my treatment a great number of suffering women of the poorer classes of different nationalities. Many among them are afflicted with different kinds of uterine trouble directly traceable to the mismanagement and ignorance of these unqualified midwives, whose notions of the most primitive rules of cleanliness and disinfection are very scanty indeed. Of late the Ottoman Government has tried to restrict the mischief by prohibiting the non-licensed women from engaging in midwifery practice but the attempts have proved futile. The unqualified *sages-femmes* still abound, thriving on the utter ignorance of the population. In Turkey generally women in labour or with uterine trouble

still shrink from calling males to their assistance; they still prefer to be treated by one of their own sex, no matter how destitute of the requisite amount of knowledge. In Constantinople itself there exists only one maternity hospital; it has been doing good work for about ten years, although statistics of its actual performances are unavailable. One maternity hospital is, however, absolutely insufficient for such a great city as Constantinople.

Regulations concerning Pharmaceutical Preparations.

All the pharmaceutical preparations made in Turkey will be henceforward subjected to an examination by the Medical Council. Only after this examination will they be offered for sale. They will have a label attached with an inscription "autorisé par le conseil médical." Those submitting the preparations to an examination will have to pay a small tax.

A School for the Blind and Deaf and Dumb.

It has been decided to create in Constantinople a school for the blind and deaf and dumb. It is said that a tax of 1 per cent. will be exacted from the salaries of State functionaries for the benefit of the school. As the Moslems are, speaking generally, of a charitable disposition and consider it part and parcel of their religious duties to help the suffering of their community, these functionaries will quite willingly pay their share. There is a difficulty, however, and it lies in the fact that the officials themselves are very frequently irregularly paid by the Government. The arrangement, therefore, is on a doubtful basis and it will not be wise to be too sanguine.

June 25th.

Obituary.

JOHN HENRY BRIDGES, M.B. OXON., F.R.C.P. LOND.

Dr. John Henry Bridges, who died at Tunbridge Wells on June 15th, was for many years actively engaged in the general supervision of Poor-law institutions in London and was consequently well known to all the medical men concerned in that particular branch of practice. He was the son of the Rev. Charles Bridges and was born at Old Newton, in Suffolk, in October, 1832. His school education was received at Rugby under the Rev. Dr. Tait, after which he proceeded to Oxford entering first at Wadham College and becoming a Fellow of Oriel College in 1855. Deciding to enter the medical profession he studied at St. George's Hospital and graduated as M.B. at the University of Oxford in 1859. From 1861 to 1869 he was physician to the Bradford Infirmary and in 1869 married Miss Mary Alice Hadwen of Halifax. In 1867 he was elected a Fellow of the Royal College of Physicians of London and in October, 1892, he delivered the Harveian oration on Harvey and his Successors. In 1869 he accepted an appointment as one of the inspectors under what was then the Poor-law Board but which has since been renamed the Local Government Board. These gentlemen are officially designated as either general or medical inspectors. Dr. Bridges to some extent combined both functions; he did not engage in purely medical inquiries such as the causation of disease or the circumstances leading up to localised outbreaks of illness, but he was occupied almost entirely in supervising the administration, medical and general, of the workhouses, the Poor-law infirmaries, and the various institutions belonging to the Metropolitan Asylums Board. In such a position it will be easily understood that he had to balance the claims of many conflicting interests and for such work he was well qualified by his calm, dispassionate judgment, kindly disposition, and general knowledge of the world.

His election to a Fellowship at Oriel College was a sufficient indication of his literary and philosophical attainments. He was, in fact, known to the reading public as the translator of several works of Auguste Comte, the founder of Positivism, rather than as a medical man. He, however, did excellent work in what has been termed that great silent conspiracy, the Civil Service, upon the members of which there has been imposed the seal of an official reticence. There is, indeed, a certain similarity between the career of Dr. Bridges and that of the late Matthew Arnold. Both held important posts as Government inspectors and both were more widely known in connexion with their literary

output than with their official duties—a fact which is doubtless in some measure to be explained by the circumstance that in this latter capacity each was true to the traditions of the service to which he belonged. Dr. Bridges was for some 20 years the medical inspector for Poor-law purposes in the metropolis, and having regard to the enormous population served by the various institutions above enumerated and to the importance which the Local Government Board doubtless attached to the reports of Dr. Bridges, the office must be regarded as involving a very high degree of responsibility in the matter of Poor-law and isolation hospital administration. Among those with whom Dr. Bridges was brought into official contact he was regarded with the greatest respect and with feelings akin to affection. He was ever on the side of progress and his influence can be traced in many of the reforms passed during his official career. When at the age of 65 years Dr. Bridges passed, like all other civil servants, into official retirement he was presented by the medical superintendents of the institutions with which he had been associated with a touching tribute in the shape of a valuable testimonial of the respect in which he and his work were held. But although this was the termination of his official career his valuable services were not long lost to the Metropolitan Asylums Board, as he was shortly afterwards nominated as one of the managers of that body, and for some years afterwards he took the deepest interest in the administration of the Board, proving himself eminently helpful and sympathetic in all which concerned the interests of the medical superintendents and the improvement of the nursing arrangements.

**CHARLES HENRY TAYLOR, M.B. LOND., L.R.C.P. LOND.,
M.R.C.S. ENG., L.S.A.,**

SENIOR SURGEON TO THE DERBYSHIRE ROYAL INFIRMARY.

Charles Henry Taylor was the eldest son of the late Alderman Taylor of The Cedars, Newport Pagnell, where he was born on Jan. 3rd, 1860. He died suddenly and unexpectedly on June 15th at Derby where he was senior surgeon to the Derbyshire Royal Infirmary. He was educated at the Crescent School, Margate, and at King's College School, where he boarded with Dr. Twentyman (at Twickenham). From there he matriculated at the University of London and entered with a large number of other students at King's College about the time when Sir Joseph Lister joined it as professor of surgery. For the next five years he lived with Mr. C. B. Kestley. A member of the staff of King's College writes: "Thoroughness and persistence were the characters of his work, which, despite his want of opportunity of holding a resident appointment at his old school, resulted in high essential success. Among his fellow students his quiet and cheerful manner gained him a general popularity and there are many old friends who will recall his kind help to them in those days." He had other qualities also which endeared him to his friends and acquaintances. He was absolutely trustworthy and led a life quite free from vice or any other mean feature, while he was an admirable musician with a sound and extensive knowledge of music, a skilled performer on the piano and on the organ, and a singer with good taste and an agreeable high baritone voice. He was naturally therefore very sociable and his society was much sought. He enjoyed heartily a good play, a good book, a good joke, or a good story, and was always ready to help to promote any object which any intimate friend had at heart, and to interest himself in it. Although he had no spontaneous affection for athletic exercises or sport, at Derby he took a keen interest in the town football team—a celebrated and successful one—and was a member of its controlling committee. While at King's College he dressed for Sir Joseph Lister in three summers (1880, 1881, 1883), and for Professor John Wood in two winters (1881-82, 1882-83), which illustrates his keenness for practical work. In 1885 he took the degree of M.B. at the University of London and soon afterwards became house surgeon to the West London Hospital and then house physician. He was asked to stay beyond the usual time. His punctuality, tact, and good sense, combined with his musical talents and good nature, made him an ideal hospital resident.

In 1869 he went to Derby as senior house surgeon to the Royal Infirmary and held the post for seven years. From then until his death he threw himself with enthusiasm into the work of the institution, especially in connexion with the

various building operations which have made it a model hospital, and with musical matters. He acted as organist to the infirmary chapel. In 1896 he joined Mr. John A. Sharp in practice and when that gentleman resigned his office of surgeon to the infirmary Dr. Taylor was elected to the visiting staff, in five years becoming senior surgeon. He did a great deal of good work but in private surgical practice found himself handicapped by the accessibility of such great surgical centres as London, Leeds, and Manchester. He was fearless in the execution of his duty. During the building operations at the infirmary already mentioned a high wall collapsed, crushing and seriously injuring several workmen. It was some time before one man could be extricated from the débris and Taylor saw to his injuries and dressed his wounds as he lay, all the time in imminent danger of being buried himself by an adjacent wall which was tottering to its fall. He had not been well for three months before his death, having suffered from several attacks of influenza. About the end of May he was being attended by Dr. R. H. Luce and afterwards consulted Sir Hugh R. Beevor. The latter recommended him to give up practice for 12 months. He then went to Newport Pagnell for a time, returning to Derby on Friday, June 15th. Mr. Sharp, who was staying at his house, says that after lunch on this Friday Dr. Taylor "had a little nap. On rising he said that he felt horribly depressed and very miserable." This conversation took place in his room and at its close he said he would go into the surgery and look through the papers that had accumulated. This was about 3 p.m. Mr. Sharp then went out on a journey, returning about 5 o'clock. From what the maid then said he went upstairs and found Dr. Taylor lying on his bed no longer alive. A post-mortem examination was made by Dr. F. B. Thornton and Dr. Luce. The organs as a whole appeared to be perfectly healthy but the heart was in an exceedingly weak condition. The cause of death was syncope. Looking back, it seems very unfortunate that the deceased when feeling, as he said, "horribly depressed and very miserable," and suffering in all probability from catarrhal or influenzal poisoning of a weak heart, should have gone soon after a railway journey into his surgery to the worrying and fatiguing work of looking over accumulated papers and correspondence. Had he gone straight to bed, rest, warmth, and open windows might have enabled him to look over his papers safely on the next day. The catastrophe is a lesson to all of us.

Dr. Taylor was unmarried. One of his characteristic acts was to join with his uncle and sister in restoring, at the expense, it is said, of about £800, the fine organ of St. Peter and St. Paul's Church, Newport Pagnell. When the writer of this account last saw him Dr. Taylor announced with glee that he was going to take a holiday at Newport and to spend much of the time in playing on this organ, then just completed. He was buried in the town of his birth on June 19th, leaving many mourners both there and at Derby.

FORBES MANSON GRANT TULLOCH, M.R.C.S. ENG.,
L.R.C.P. LOND.

LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

THOSE who knew the late Lieutenant Tulloch personally will feel that by his untimely death we have not only lost a charming personality but also a very promising worker in a difficult department of research and one who was strenuous and faithful in his work and duty. Many opportunities occurred at St. Mary's Hospital of watching the development of his inclinations towards work on the scientific side of medicine. He frequented the pathological laboratory before it was necessary for him to do so and practised himself in the ordinary diagnostic methods in use, and when he later became demonstrator of pathology it was obvious that his real bent lay rather in this direction than towards purely clinical work. He had clever fingers, so that his technique quickly surpassed the average and his microscopical manipulations reached a high level even at that time. After qualifying and obtaining admission to the Royal Army Medical Corps he studied for some time under Major W. B. Leishman and when he was sent to Uganda to work at sleeping sickness it was felt that his future success was assured. As it is, his completed work on that subject shows that his ability, enthusiasm, and patience would have borne fruit had he

been spared. A paper written by him in collaboration with Lieutenant Gray on the Multiplication of the Trypanosoma Gambiense in the Alimentary Canal of Glossina Palpalis has been published in vol. vi., of the Reports of the Sleeping Sickness Commission; and another paper by him is in the hands of the Tropical Diseases Committee of the Royal Society and will soon be published. Shortly before his death he was quite cheerful and courageous, although he knew only too well that he was doomed. Such an attitude in one who was young and gifted has no little of the heroic in it.

WILLIAM BATES RAMSDEN, B.Sc., M.B., CH.B. VICT.

BY the untimely and sudden death of William Bates Ramsden on June 29th the University of Manchester has been deprived of the services of one who promised to enhance the reputation of the Manchester school by his researches in sanitary chemistry. He had prepared himself for a specially useful career by taking successfully complete courses in chemistry and in medicine. In 1897 he obtained a first class in the final B.Sc. examination in the Honours School of Chemistry and in 1903 he passed the examination for the degree of M.B., Ch.B. of the University of Manchester. For more than three years he had given considerable attention to the application of chemistry to hygiene and was appointed in 1904 Research Fellow in Sanitary Chemistry at the Public Health Laboratory. In 1905 he succeeded Mr. D. L. Chapman who for the previous three years had occupied with marked success the post of lecturer on sanitary chemistry. Dr. Ramsden had for the last year been specially engaged in researches on foods, preservatives, and adulterants. This work was already yielding results of great practical importance. A short account of his new methods of estimating formaldehyde appeared in the Memoirs and Proceedings of the Manchester Literary and Philosophical Society (Vol. XLIX., No. 16, 1905) and in the Archives of the Public Health Laboratory (Vol. I.). It is hoped that the notes which he has left of his larger work on the subject of formaldehyde in milk will be sufficiently complete to allow of its publication. Dr. Ramsden, who was in his thirtieth year, had just been speaking to two members of his class when he suddenly fell dead from failure of the heart. He was an inspiring and successful teacher and his death is deeply regretted by all his colleagues and pupils.

Medical News.

UNIVERSITY OF OXFORD.—At examinations held recently the following candidates were successful:—

FIRST M.B. EXAMINATION

Organic Chemistry.—P. L. Gibson, Trinity; W. F. Harvey, Balliol; T. B. Heaton, Christ Church; G. L. Inkster, Balliol; C. H. G. Martin, Magdalen; A. S. Roe, Balliol; and K. H. Udall, Queen's.
Materia Medica and Pharmacy.—T. B. Batchelor and J. L. Birley, University; F. W. Browne, Wadham; P. N. Cave, University; A. R. Chavasse, Hertford; N. G. Chavasse, Trinity; G. H. Cross, Balliol; A. W. Donaldson, Hertford; H. O. S. Gibson, New College; N. Glover, Trinity; T. B. Heaton, Christ Church; W. D. Kennedy, University; C. H. G. Martin, Magdalen; A. E. Mavrogordato and S. F. Moore, Trinity; W. J. Oliver, Oriel; E. L. Pearce-Gould, Christ Church; W. J. Pearson, University; E. P. Poulton, Balliol; A. S. Roe, Christ Church; H. W. Scott-Wilson, Queen's; O. L. V. Simpkinson, Corpus Christi; C. J. G. Taylor, University; D. B. Todd, Lincoln; W. W. Wagstaffe, New College; and R. O. Ward, Queen's.

Human Anatomy and Human Physiology.—C. N. Binney, Corpus Christi; H. J. B. Frv, Magdalen; H. E. Gibson, Queen's; A. E. Mavrogordato, Trinity; G. H. Nelligan, Exeter; H. P. Newsholme, Balliol; E. W. M. Phillips, Jesus; A. H. Savage, New College; O. L. V. Simpkinson, Corpus Christi; S. S. Strahan, Keble; and T. S. Wright, Brasenose.

SECOND M.B. EXAMINATION

Pathology.—G. H. H. Almond, Hertford; B. E. A. Batt, Trinity; G. D. H. Carpenter, non-collegiate; H. A. Cockayne, Balliol; M. Davidson, Trinity; C. G. Douglas, Magdalen; M. W. Flack, Keble; J. F. Hornsey, Wadham; F. Howson, non-collegiate; E. L. Kennaway, New College; and C. T. Raikes, Trinity.

Forensic Medicine and Public Health.—C. Beards, Jesus; E. L. Kennaway, New College; G. M. Johnson, Magdalen; A. S. MacNalty, non-collegiate; H. C. G. Semon, Magdalen; and H. S. Souttar, Queen's.

Medicine, Midwifery, and Surgery.—O. A. R. Berkeley-Hill, Trinity; D. Davidson, Brasenose; S. Nockolds and L. J. J. Orpen, Keble; and H. S. Souttar and A. G. Thompson, Queen's.

UNIVERSITY OF CAMBRIDGE.—At a Congregation on June 19th the following degrees were conferred:—

M.B. and B.C.—F. A. G. Jeans, St. John's; and R. P. Cockin, Gonville and Caius.

During the academic year just closed 22 candidates received the degree of M.D., five the degree of Sc.D., three the degree of M.C., 62 the degree of M.B., and 67 the degree of B.O.—Mr. C. T. R. Wilson, F.R.S., lecturer at the Cavendish Laboratory, has been re-elected to a Fellowship at Sidney Sussex College, and the Rev. T. O. Fitzpatrick, assistant demonstrator, has been elected President of Queen's College.

UNIVERSITY OF LEEDS.—At a congregation of the University held on June 30th the degrees of Bachelor of Medicine and Bachelor of Surgery were conferred on the two following graduates in medicine and surgery of the Victoria University who had been students at Leeds:—

Oscar Bagster Trumper and Joshua Williamson.

At the First Examination for the degrees of M.B. and Ch.B. the following candidates were successful:—

Parts I. and II.—J. P. Brown, J. B. Fisher, H. V. Lamb, N. V. Mitton, B. A. Slowcombe, G. V. Stockdale, N. S. Twist, and B. Ward.

Part I.—R. D. Fairclough.

Part II.—H. N. Ingham, J. P. Musson, and F. W. Nunneley.

The council of the University, acting on the recommendation of the board of the Medical Faculty, has decided to create five new lectureships in connexion with the institution of the school of dentistry. These are lectureships on (1) dental surgery; (2) operative dental surgery; (3) dental anatomy and physiology (including dental microscopy); (4) dental mechanics (including practical dental mechanics); and (5) dental metallurgy (including practical dental metallurgy). During the current week the written examination of the second and final M.B. Ch.B. examinations will be completed. The *vis à voce* and practical parts of the second examination will also be conducted during the week. In the course of next week the clinical examinations and the other parts of the final examinations will be concluded.

TRINITY COLLEGE, DUBLIN.—At examinations held in Trinity term the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part I.—William Pearson, Robert E. Wright, George F. Graham, John A. L. Hahn, Allman J. Powell, Frederick Stevenson, Henry de C. Dillon, Charles H. O'Rourke, Edward C. Stoney, Richard G. S. Gregg, James C. C. Hogan, Wilfred J. Dunn, Henry J. Keane, John W. Lane, William S. Thacker, John H. Morton, Edmund H. Sheehan, James E. M'Farlane, Joseph H. Elliott, and Eleanor E. Finegan.

Part II., Surgery.—John C. P. Beatty, Francis R. Coppinger, Thomas H. Peyton, Edward Gibbon, Lily A. Baker, Thomas L. de Courcy, Henry D. Drennan, George Dougan, Ernest C. Phelan, Ernest C. Crawford, Thomas J. Cobbe, John B. Whelan, and Ernest D. Caddell.

Part II., Midwifery.—Gustav W. Thompson, Edward Gibbon, Robert B. Jackson, Thomas L. de Courcy, Cecil T. Conyngham, Henry B. Leech, Henry D. Woodroffe, George Dougan, Wilfred L. Hogan, Thomas B. W. MacQuaide, Charles G. Sherlock, Theodore C. Somerville, Francis W. H. Bigley, Thomas J. Cobbe, John B. Whelan, Madeleine S. Baker, Albert J. T. M. Creery, James E. M'Farlane, Ernest C. Crawford, and Joseph H. Elliott.

INTERMEDIATE MEDICAL EXAMINATION.

Part I.—John L. Phipps, Richard P. Hadden, Albert J. Stals, Thomas A. Hughes, Adams A. M'Connell, Herbert V. Stanley, Cecil P. Smyly, William A. R. Spong, Duncan B. Hunter, Peter H. Lemaas, Arthur B. Laird, John D. Kernan, George B. M'Hutchison, William N. Watson, Richard J. Attridge, Eric J. Powell, Charles G. S. Baronsfeather, Frederick R. Sayers, and Harold T. Sugars. The Purser Medal in Institutes of Medicine was awarded to Richard P. Hadden.

PRELIMINARY SCIENTIFIC EXAMINATION.

Physics and Chemistry.—Herbert de L. Crawford, William L.A. English, Hilary Müller, John H. Woodroffe, Edward P. Allman-Smith, Ralph T. St. J. Brooks, Roelof A. Albertyn, John Gardiner, Charles M. Finny, Adrian Stokes, David L. M'Cullough, George Elliott, Victor G. Best, Walter C. Adam, John Ronaldson, Marius A. Diemont, Arthur C. Hallows, George F. C. Healy, James N. Greene-Nolan, Euphon M. Maxwell, Brindley H. Moore, and George J. Meldon.

Botany and Zoology.—Charles W. M. Kenny, Roelof A. Albertyn, William L.A. English, Adrian Stokes, Dorothea M. Franks, Benjamin A. Molyneux, Vicars M. Fisher, Charles M. Finny, John H. Woodroffe, Ernest W. G. Young, Francis J. A. Keane, Edmund F. Lawson, John Ronaldson, Thomas L. Bookey, Victor W. T. McGusty, Patrick Murphy, John G. Dods, James C. Kelly, Louis Richard, Hugh M'C. Fleming, James M. Elliott, Henry P. Harpur, Frank Crobie, and Edgar N. Bateman.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basil:* Dr. Rudolf Stähelin has been recognised as *privat-docent* of Medicine.—*Berlin:* Dr. Albert Plehn has been

granted the title of Professor in recognition of his researches on malaria.—*Bonn:* Dr. Rudolf Klapp, one of the surgeons in the University Surgical Clinic, has been promoted to an honorary Extraordinary Professorship.—*Craon:* Dr. F. J. Novotny has been recognised as *privat-docent* of Oto-Rhino-Laryngology and Dr. Adam Wizek as *privat-docent* of General and Experimental Pathology.—*Freiburg (Switzerland):* This University is shortly to be provided with a medical faculty.—*Göttingen:* Dr. Franz Schiek, *privat-docent* of Ophthalmology, has been granted the title of Professor.—*Heidelberg:* Dr. Ludwig Schreiber has been recognised as *privat-docent* of Ophthalmology. Dr. Martin Jacoby, *privat-docent* of Pharmacology, has been granted the title of Professor. Dr. Narath of Utrecht has been offered the chair of Surgery.—*Innsbruck:* Dr. Oscar von Wünscheim has been recognised as *privat-docent* of Hygiene.—*Munich:* Dr. Robert Rösle of Kiel has been recognised as *privat-docent* of Pathological Anatomy.—*Prague (Bohemian University):* Dr. Josef Cislis has been recognised as *privat-docent* of Rhinology and Laryngology.—*Strasbourg:* Professor Chiari of Prague, who was well known to several generations of English and American post-graduate students while he was demonstrator of pathological anatomy in Vienna, has been appointed to succeed Professor von Recklinghausen in the chair which he is resigning.

THE PRESENTATION TO DR. A. E. JONES.—The movement recently instituted with a view to compensate Dr. A. E. Jones for his expenses in his late ordeal was brought to a conclusion on July 2nd, when a small gathering of subscribers was held at the house of Sir Victor Horsley, treasurer of the fund. Mr. John Tweedy, President of the Royal College of Surgeons, presided, and amongst those present were Dr. F. T. Roberts, Dr. H. Radcliffe Crocker, Mr. P. Sidney Spokes, Dr. Herbert Tilley, Dr. Andrew Duncan, Mr. George Pernet, and Mr. E. S. Weymouth. Mr. Tweedy, in presenting Dr. Jones with a cheque for £144, said that the meeting of Dr. Jones's professional friends embodied their deep sympathy with him in his recent terrible trial and symbolised their absolute confidence in his high integrity. The charge had been triumphantly disproved in a court of law and he congratulated Dr. Jones in the name of his professional brethren most heartily on the successful issue of a most painful experience. Dr. Roberts in a few remarks spoke of the high esteem in which he held Dr. Jones and added, as a former teacher, his congratulations. Dr. Jones made a short reply in which he said that apart from personal considerations all such movements as this were of the utmost value in forwarding the unity of the profession. He thanked the subscribers most heartily for their sympathy and support.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held on June 28th at Caxton House, Westminster, Dr. F. H. Champneys being in the chair.—A letter was read from the Local Government Board forwarding a copy of a communication from Mr. J. R. S. Park, medical officer of health of Dukinfield, as to the disinfection of the clothing of midwives who have been in attendance on cases of puerperal fever. After some discussion the matter was referred to the standing committee. A letter from Dr. E. Walford, medical officer of health of Cardiff, as to examining in Welsh was considered and it was decided that Dr. Walford should be asked to state whether in his opinion the difficulty experienced by certain Welsh candidates in taking their examination in English would be met by the presence of an interpreter at the oral examination. A letter was considered from Mr. J. E. Gordon, honorary secretary of the Salisbury division of the British Medical Association, inclosing copy of a resolution passed by the division as to the form of the record of sending for medical help prescribed by Rule E. 19 (b). The Board decided that Mr. Gordon should be informed that the Board has already forwarded to the Privy Council for its approval a draft revision of the rules which in part meets the objections raised to Rule E. 19 (b). The Board decided in regard to the question of holding examinations in Dublin that the Privy Council should be informed that the Board has carefully considered the memorandum handed to the Lord President during a recent visit to Dublin, urging the holding of the Board's examinations in Dublin. The Board is of opinion that it is not within the contemplation of the Act that any action should be taken by it outside the area defined by the Act and that therefore it would be acting *ultra vires* in holding any examination except at centres in England and

Wales. It would point out that the proposal to increase the examination fee above the present fee of one guinea if the examination were held in Ireland is contrary to Section V. of the Midwives Act. The Board suggests that as it is now proposed to defray the expenses of an examination in Dublin by a special contribution the difficulty might be met by those interested in the matter paying the travelling expenses of candidates to a centre in England.

ISOLATION HOSPITAL FOR TEIGNMOUTH.—Bilton Hospital, Teignmouth, which has been erected by the urban district council for the reception of infectious cases, was formally opened on June 28th in the presence of a large company. The hospital, which stands on an acre and a half of land, contains four wards, administrative block, laundry, disinfectant, mortuary, &c. The cost of the building, exclusive of land, has been £2630, and the institution in case of emergency can accommodate 24 patients.

PROSECUTION OF A HERBALIST.—A herbalist of Cefn, South Wales, was recently prosecuted by the Society of Apothecaries of London for practising as an apothecary without being legally qualified. The defendant was fined the full penalty of £20, exclusive of costs. The herbalist in February, 1906, was censured by a coroner's jury at Cefn for having prescribed and sold medicines to a woman who had died from gastric ulcer and peritonitis.

WEST LONDON HOSPITAL AND POST-GRADUATE COLLEGE.—The annual dinner of this hospital and college was held on June 28th at the Trocadéro Restaurant, Piccadilly-circus, London. Mr. Stephen Paget, surgeon to the hospital, presided, and a thoroughly enjoyable evening was spent by a large company. Among those present were Inspector-General H. M. Ellis (Director-General of the Royal Navy Medical Service), Fleet Surgeon Bell, Surgeon-General A. M. Branfoot, I.M.S., Mr. G. F. Marshall (chairman of the house committee of the hospital), Mr. Danvers Power, and many members of the past and present honorary staffs of the hospital. After the loyal toasts Mr. D. J. Armour, assistant surgeon to the hospital, proposed "The Imperial Forces" in a stirring speech, in the course of which he laid stress upon the prominent part played in the recent Boer war by his compatriots the Canadians. The Director-General of the Royal Navy Medical Service, in reply, said that the Royal Navy Medical Service owed a deep debt of gratitude to the West London Hospital, and more especially to those of its staff who were connected with the Post Graduate School. Many navy medical officers had, he said, passed through that school and many more were waiting to enter when the exigencies of the service permitted. The chairman then submitted the toast of the evening, "Prosperity to the West London Hospital," and alluded to the great development of the institution during the 50 years that had elapsed since it was inaugurated. The task of obtaining the necessary money, was he said, a great burden upon those who controlled its destinies, and he proceeded to sketch in terms of real eloquence the ideal building which he saw springing up on the site of the West London Hospital if only the necessary funds were forthcoming. Mr. Marshall replied and was driven to admit regretfully that although the story of the hospital was persistently one of progress the work of reconstruction was not going on unimpeded, for the London County Council had taken a course of action which would entail entirely new plans upon the building committee. Surgeon-General Branfoot then proposed "The Post-graduate College," and in doing so remarked that both the Navy and the Army Medical Services recognised the importance of post-graduate work but no body appreciated it more than the members of the Indian Medical Service. A large number of them sought the aid of the college for instruction in the up-to-date methods and treatment of disease. Mr. L. A. Bidwell, surgeon to the hospital and dean of the college, in reply, said that during the last 12 months 226 new members had joined the college and the total number of those who had worked there since its formation in 1893 was over 1000. Of these about 300 had been officers in the Navy, Army, and Indian Medical Services and 250 others had come from the colonies and foreign countries. Mr. C. A. Lees also replied to this toast, testifying warmly to the value that it was to the general practitioner to have the run of an institution where he was welcomed as a practical student of medicine. Mr. Danvers Power replied humorously to the toast of the

guests, which was proposed by Dr. A. E. Russell; and Dr. G. P. Shuter carried his audience with him in a thoughtful eulogy of the merits of the chairman. Those present at the dinner were fortunate in having really interesting as well as brief speeches to listen to. Mr. Bidwell's figures, in particular, much impressed his hearers who came away convinced that the hospital and college were doing thoroughly good work with which it was an honour to be associated.

THE PROPOSED REMOVAL OF ST. GEORGE'S HOSPITAL.—At a meeting of a special court of governors on June 26th, held in the board-room of the hospital under the presidency of Lord Plymouth, the question of the removal or the rebuilding of St. George's Hospital was discussed. Mr. A. A. West, after referring to the large sum which the Duke of Westminster's estate board asked for their interest in the site, said that there were three alternative schemes. First, to remain where they were, carrying on their work as well as they could, which would cost £37,700; secondly, to buy up the leasehold interest of the houses at Knightsbridge, which would cost £120,000; and thirdly, to rebuild the hospital afresh on the present site which would cost £350,000. The minimum price that he suggested as the one at which it would be desirable to move was £400,000. If they did not sell their site, sooner or later they must appeal to the public for £350,000. He moved—

That this court thinks it advisable that the hospital should be removed to another site, provided a suitable one could be found at a certain figure.

If that motion were carried, he proposed to move that the sum at which it would be desirable to move was a minimum of £400,000. Mr. Thorp seconded the motion and a long discussion ensued. Lord Eustace Cecil said he did not think that the matter ought to go on until the whole of the governors had had an opportunity of carefully considering the formidable figures which had been placed before them. Mr. Timothy Holmes said that to keep the matter before the public would do an immense amount of injury to their present position. Two years ago they passed a resolution to the effect that it was not desirable in existing circumstances to remove the hospital from its present site and he asked the governors to act upon that resolution now. The Duke of Grafton suggested that the resolution passed two years ago should be reaffirmed and it was finally resolved:—

That this court having had no adequate offer for the hospital site submitted to it the resolution passed at the court of governors in 1904 be reaffirmed.

SOCIETY FOR THE PREVENTION AND CURE OF CONSUMPTION IN THE COUNTY OF DURHAM.—The seventh annual meeting of the governors of this society was held at the Sanatorium, Stanhope, on June 30th. Lord Barnard (the President) was in the chair and there was a good assembly of representatives from many places throughout the county. —Dr. W. Robinson (Sunderland), chairman of the committee, in moving the adoption of the reports, said that on the foundation of the society eight years ago exception was taken to its present name as consumption was then believed to be incurable but there were cured patients present who had been at work regularly for three, four, and even five years. The death-rate from consumption in the administrative county had diminished over 30 per cent. during the last 11 years owing to better housing and the wider recognition of the necessity for fresh air and sufficient ventilation, but there had been little reduction in the rate of the four county boroughs of Sunderland, Gateshead, South Shields, and West Hartlepool, because of the density of the population in their slums which are veritable hotbeds of the disease. As it was almost impossible to transform all these slums into healthy abodes he urged that special homes for advanced cases should be provided by the local authorities. The disease would then decline. Following the example of Brighton Manchester was about to utilise the empty wards of its fever hospital for this purpose and the medical officer of health, the speaker said, urges Sunderland to do the same. Tuberculosis caused 2522 deaths in the county in 1904, 1498 of which were due to disease in the lung. The Stanhope Sanatorium contained 45 beds; 224 patients applied for admission but only 163 could be admitted. As there were between 5000 and 6000 consumptives in the county another sanatorium was much needed for women and children, so that the present one might be used for men only. Funds for this purpose were urgently needed. The Bishop of Richmond seconded the

adoption of the reports, which was carried. The address of the secretary is Mr. F. Forrest, 54, John-street, Sunderland.

APOTHECARIES' HALL OF IRELAND.—The summer medical examinations will commence with the First Professional on Monday, July 16th, 1906. All entries should be made at once with the Registrar, 40, Mary-street, Dublin.

PRESENTATION TO A MEDICAL PRACTITIONER.—On June 27th the members of the Camborne (Cornwall) branch of the St. John Ambulance Association presented Mr. William Blackwood, M.B., B.Ch. Edin., with a barometer suitably inscribed as a mark of appreciation of his services as honorary lecturer.

MEDICAL MAGISTRATES.—Mr. Hugh Lewis Hughes, L.R.O.P., L.R.C.S. Edin., L.F.P.S. Glasg., L.S.A., of Downais, and Mr. Thomas William Thomas, M.R.C.S. Eng., L.S.A., of Caerphilly, have been placed on the commission of the peace for the county of Glamorgan.—Mr. William Banks, M.B. Lond., M.R.C.S. Eng., has had his name placed on the commission of the peace for the borough of Falmouth but he has written to the town clerk stating that he does not desire the appointment.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Infant Life Protection.

A BILL to amend the Infant Life Protection Act, 1897, has been brought into the House of Commons by Mr. STAVELEY HILL, with the support of Sir JOHN KENWAY, Mr. ARTHUR LEE, Mr. CLAUDE HAY, Mr. WALROND, Mr. RAMSAY MACDONALD, Mr. HILLS, and Mr. NICHOLLS. The memorandum which has been issued with the printed text of the Bill explains its object. By the Infant Life Protection Act, 1897, a person receiving for hire or reward more than one infant under five years of age for the purpose of nursing or maintaining such infants apart from their parents for longer than 48 hours, or receiving an infant under two years of age to bring up in consideration of a sum of money not exceeding £20 paid down, is obliged to give notice thereof within 48 hours to the local authority, as defined in such Act. Such local authority is obliged to appoint inspectors to inspect such infants. Failure to give such notice renders the offender liable in the first-mentioned case to a fine of not less than £5 or to imprisonment for not more than six months and in the second-mentioned case only to forfeiture of the amount received. If any infant, as aforesaid, is kept in any house or premises which are so unfit or overcrowded as to endanger the child's health, or is retained or received by any person who by reason of negligence, ignorance, or other cause is so unfit as to endanger the child's health, the local authority may order the removal of the infant to the workhouse or a place of safety until the latter can be restored to the relatives or guardians or otherwise lawfully disposed of. The object of this Bill is to extend the provisions of the Act to cases where only one child is taken in to be nursed or maintained and to any child received in consideration of a sum of money paid down, whatever the amount may be; to raise to seven years the age limit of children within the Act; to render any person failing to notify the reception of an infant, adopted in consideration of a lump sum payment, liable to fine or imprisonment as above mentioned, as well as to forfeiture of the amount received; to make it clear that the inspection of children within the Act shall extend up to their reaching seven years or earlier removal by the local authority; to enable the local authority to remove an infant kept by a person who is unfit, by reason of character or otherwise, to have such care and maintenance, or who is in a house or premises unsuitable for the purpose, although such person or premises are not so unfit as to endanger the child's health; and to require notice to be given of all changes of residence of a person having the care or custody of children within the Act under penalty of imprisonment or fine.

The Board of Education and the Vaccination of Teachers.

In the new code of regulations for public elementary schools issued on June 30th by the Board of Education a decision of importance is announced with reference to the vaccination of teachers. It is stated that it has been represented to the Board that in view of recent legislation with regard to vaccination there is a hardship in the continuance of its long standing requirement that every teacher or pupil teacher employed in a public elementary school shall have been duly vaccinated. While the Board feels that it is not unreasonable to take greater precautions against infection where a number of children are brought together within the limited space of a schoolroom than might be necessary in other circumstances it is prepared to leave the responsibility in this matter to the local education authorities by whom the teachers are employed. It has therefore inserted a

provision in the Code relaxing the obligation to be vaccinated in the case of teachers who have declared themselves to have a conscientious objection to vaccination. A similar provision has been inserted in the regulations for the instruction and training of pupil teachers. The fact that such a teacher is unvaccinated will in all cases be kept on record by the Board and it must be clearly understood that the Board will not recognise any such teacher in any school except with the consent of the local education authority, whose duty it will therefore become to satisfy itself that the precaution of vaccination may be dispensed with without risk to the children with whom the unvaccinated teacher may be brought into contact.

Another Bill for the Registration of Nurses.

Mr. CLAUDE HAY has brought forward a Bill to regulate the qualification and registration of nurses. There is, of course, no chance of its becoming law or even of its being discussed in Parliament this session, but the text is being circulated for the information of Members generally. The operative clauses are these: 1.—(1) From and after the first day of January, one thousand nine hundred and eight, no person shall practise as a registered nurse unless such person be registered under this Act; any person so acting, without being registered under this Act, shall be liable, on summary conviction, to a fine not exceeding ten pounds. (2) No person shall be registered under this Act until such person has complied with the rules and regulations to be laid down in pursuance of this Act, and unless such person shall have attained the age of twenty-four years, and shall have had a training at a recognised training school for nurses for a period of not less than three years, and shall produce a certificate from a training school to the effect that the curriculum laid down by the Central Board has been complied with, and shall also pass the examination prescribed by the Central Board. 2. Any person who, within two years from the date of this Act coming into operation, claims to be registered under this Act, shall be so registered provided that such person holds a certificate of at least two years' training from any institution recognised by the Central Board, or produces evidence, satisfactory to the Board, that, at the passing of this Act, such person had been for at least five years in *bona fide* practice as a trained nurse, and bears a good character, and produces testimonials of efficiency satisfactory to the Central Board from three registered medical practitioners under whom she has worked. 3. Any person who shall produce evidence satisfactory to the Board of having been trained as a nurse in any part of the British dominion beyond the seas, shall be registered, provided that such person shall have passed an examination approved by the Board, and bears a good character, and shall comply with the provisions of this Act with regard to the payment of fees, provided also that such part of the dominion admit to its register British registered nurses on reciprocal terms. 4. On the passing of this Act, the Lord President of the Council shall take steps to secure the formation of a Central Board, which shall consist of—(1) One lay person to be appointed for a term of three years by the Lord President of the Council to represent the general public. (2) One registered medical practitioner to be appointed for a term of three years by the Lord President of the Council, to represent the hospitals and infirmaries of Great Britain and Ireland. (3) One registered medical practitioner to be appointed for a term of three years by the English members of the General Medical Council as the representative for England. (4) One registered medical practitioner to be appointed for a term of three years by the Scottish members of the General Medical Council as the representative for Scotland. (5) One registered medical practitioner to be appointed for a term of three years by the Irish members of the General Medical Council as the representative for Ireland. (6) One registered medical practitioner to be appointed for a term of three years by the Council of the Medico-Psychological Association of Great Britain and Ireland. (7) One representative to be appointed for a term of three years by the Council of the Royal British Nurses' Association. (8) One representative to be appointed for a term of three years by the Council of the Queen Victoria Jubilee Institute. (9) One registered medical practitioner to be appointed for a term of three years by the Council of the British Medical Association. (10) Three registered nurses who are past or present matrons of any hospital or infirmary in the United Kingdom (other than hospitals for fever or infectious cases) which contains not fewer than one hundred beds, and where nurses are trained and granted a certificate of such training, to be elected for a term of three years, one of such registered nurses to be elected by and representative of the matrons of such hospitals and infirmaries in England and Wales, one of such registered nurses to be elected by and representative of the matrons of such hospitals and infirmaries in Scotland, and one of such registered nurses to be elected by and representative of the matrons of such hospitals and infirmaries in Ireland. (11) One registered nurse who is past or present matron of any hospital in the United Kingdom for fever or infectious cases, where nurses are trained and granted a certificate of such training, to be elected for a term of three years by the matrons of such hospitals. (12) Three registered nurses to be elected for a term of three years by the registered nurses resident within the United Kingdom, one of such registered nurses to be elected by and representative of the registered nurses resident in England and Wales, one of such registered nurses to

be elected by and representative of the registered nurses resident in Scotland, and one of such registered nurses to be elected by and representative of the registered nurses resident in Ireland.

HOUSE OF COMMONS.

WEDNESDAY, JUNE 27TH.

The Poisons and Pharmacy Bill.

Mr. WINTREY asked the Prime Minister whether, having regard to the fact that in addition to the Government Poisons and Pharmacy Bill there was in the House another Bill for amending the Pharmacy Acts and that both Bills were objected to in their present form, he would arrange for the two Bills to be referred to a Select Committee, so that a full investigation of the subject matter of the Bills might be assured.—Mr. GLADSTONE answered: My right honourable friend has asked me to answer this question. I do not think there is any need to refer the two Bills to a Select Committee. The points needing detailed investigations have already been fully considered by a departmental committee and the facts relating to the questions arising on Clause 4 of the Poisons and Pharmacy Bill are already fully known and do not require further investigation by a committee.

The Care of Criminal Lunatics.

Mr. MARNEAM asked the Secretary of State for the Home Department whether, in view of the recent murder at Camberley and the propinquity of His Majesty's Broadmoor Criminal Lunatic Asylum, greater care would be taken in future to ascertain that prisoners before being discharged could with safety to the general public be allowed at large.—Mr. GLADSTONE answered: I can assure the honourable Member that there is no ground for the suggestion that there is any want of care in discharging criminal lunatics from Broadmoor. If a lunatic is confined "during His Majesty's pleasure"—so that he can be discharged only by order of the Secretary of State—the utmost care is taken in the few cases where the question of release can be entertained at all, to ascertain that the patient's recovery is of a permanent character and that he can be allowed at large without danger to the public. An undertaking is obtained from some trustworthy relative or other person to look after the patient and to report periodically how he is, and if any sign of a relapse is reported the discharge is revoked and the patient brought back. There are, however, some criminal lunatics not detained during His Majesty's pleasure but under sentence for a definite term only. These cannot, generally speaking, be detained in Broadmoor after the sentence expires. They have to be removed to local asylums and then are under the ordinary lunacy law. I have no longer any control over their discharge which rests with the local asylum authorities.

THURSDAY, JUNE 28TH.

Sleeping Sickness.

Mr. CATHCART WASON asked the Under Secretary of State for the Colonies whether, in view of the continued prevalence and fatal character of sleeping sickness about Entebbe, he would consider the advisability of removing the seat of Government from there to Kampala, the ancient and more convenient capital, and less exposed to the disease.—Mr. CHURCHILL answered: We have not been led to form the opinion that Kampala would be a more convenient capital or less exposed to the disease of sleeping sickness.—Mr. CATHCART WASON also asked the Under Secretary of State for the Colonies whether any steps were being taken in Uganda to prevent the spread of sleeping sickness by drawing cordons round infected districts, by destroying the breeding places of the particular fly that carried the disease, or especially by discouraging settlement round the lake or by stagnant water.—Mr. CHURCHILL replied: The very full and careful investigations which, as the honourable Member is no doubt aware, are being conducted under the supervision of the Royal Society do not indicate that it will be practicable to prevent the spread of sleeping sickness by the methods referred to in the question. The Secretary of State is advised that the only means of arresting the spread of the disease which would be practicable would be by the discovery of some treatment, curative or preventive, capable of being applied to man. This matter is now engaging the attention of the Tropical Diseases Committee of the Royal Society.—Mr. CATHCART WASON further asked the Under Secretary for the Colonies whether he was aware of the fact that sleeping sickness had almost depopulated the islands in Lake Victoria; that recently a forest concession had been granted of a large island there; and whether, in order to save natives from risk of death from employment on the concession and to prevent the spreading still further of the disease, stringent instructions would be transmitted to the Commissioner.—Mr. CHURCHILL replied: It is lamentably true that sleeping sickness is rife on Lake Victoria, though I cannot say whether any islands have been actually depopulated. No report of the concession referred to by my honourable friend has yet been received.

Medical Officer for Glasgow Post Office.

Mr. WATT, on behalf of Mr. CLERLAND, asked the Postmaster-General whether he was now in a position to state the number of medical officers he proposed to appoint to carry out the duties formerly performed by the Post Office medical officer for Glasgow and the respective districts he proposed to allocate to each: and whether, having regard to the present position of affairs, he could see his way to expedite the appointments proposed to be made.—Mr. BUXTON, in reply, said: I propose to appoint six medical officers for Glasgow. Full particulars of the respective districts can be obtained by candidates from the Postmaster of Glasgow. In regard to the latter part of the question I will answer it in reply to a question of which notice has been given by Mr. LAMONT.

Mr. LAMONT asked the Postmaster-General whether he could now see his way to fill the vacant posts of medical officers to the Glasgow post-office in order to relieve Scottish Members of the burden of correspondence placed on them by the applications of medical men from all parts of the country.—Mr. BUXTON replied: As soon as it was possible to decide into how many districts Glasgow should be divided for medical purposes instructions were at once given that the six vacancies should be advertised in the usual way and that applications be invited within seven days. These applications are to be sent to the Postmaster at Glasgow and applications already received, either locally or at headquarters, will be considered unless in view of the altered circumstances they are withdrawn. The appointments will be

made as soon as possible; but the number of applications is enormous and the selections will necessarily take time. I am anxious to relieve honourable Members of the burden of correspondence thrown upon them in connexion with these medical and other appointments for their own sake, and, I may add, for my own also. I ventured to suggest in the House in the debate on the Post-office Estimates that the present system of approaching Members in order that they should bring pressure to bear in regard to these and other appointments was very much to be deprecated and I hope I shall have the general sense of the House in discouraging the system so far as possible.

Mr. WATT asked the Postmaster-General whether he had taken into consideration the advisability of appointing one or more female doctors to the position of medical officers to the Post-office at Glasgow.—Mr. BUXTON said: I do not think it would be advisable to appoint female medical officers to any of the six districts into which Glasgow will be divided.

The National Vaccine Establishment.

Sir WILLIAM COLLINS asked the President of the Local Government Board whether he would grant a return showing so far as was known the original sources of the various stocks of lymph which had been, or were being, employed by the National Vaccine Establishment, indicating those strains which were no longer in current use.—Mr. JOHN BURNS answered: As I have stated in reply to previous questions, the usual method of renewing lymph supplied from the National Vaccine Establishment is by vaccinating calves with vaccine lymph obtained from children, but in some instances the lymph has been obtained from abroad, and in such cases it would usually not be practicable to give its original sources. In these circumstances I do not think that a Parliamentary return of any value could be given. I may, however, state that in no case is lymph used at the establishment unless it has been passed through a series of calves.

MONDAY, JULY 2ND.

Queen Alexandra's Imperial Military Nursing Service.

Mr. MORTON asked the Secretary of State for War whether he proposed to make reductions in the Queen Alexandra's Imperial Military Nursing Service, seeing that the numbers employed in military hospitals were far in excess of the requirements of the sick and that much public money could be thereby saved.—Mr. HALDANE replied: The establishment of the Queen Alexandra's Imperial Military Nursing Service was fixed to provide for the efficient nursing of the sick in military hospitals at home and abroad and to establish in connexion with these hospitals nurse training schools for the men of the Royal Army Medical Corps. Increased responsibilities in both respects have been delegated to the nursing service. The distribution of the staffs has been decided upon by the civil matrons of the Nursing Board and all matters relating to army nursing form the subjects of recommendation by that board and the number is not, in the opinion of my expert advisers, in excess of the requirements. It must be remembered that the standards of the medical care and treatment which are requisite for the sick have risen during the last few years and that the improvement is resulting not only in more humane methods but in a saving of public money which is not less substantial because it is indirect.

Vaccination Exemptions.

Mr. LUPTON asked the Secretary of State for the Home Department whether Captain Gravener, who said he would not give certificates of exemption from vaccination, was still a magistrate; whether his attention had been called to Dr Tinker, a magistrate sitting on the Hyde bench, who declared on June 25th, 1906, a conscientious objection to give certificates of exemption from vaccination; and whether he would take any steps to enforce the law.—Mr. GLADSTONE answered: I am informed that Captain Gravener stated that he would not sit when applications for certificates of exemption were under consideration. When the matter was first brought to my notice I sent the papers to the Lord Chancellor and there is no further action for me to take in the matter. I have made inquiry into the case at Hyde referred to by my honourable friend and I find that after some conversation with the applicant Dr. Tinker withdrew from the bench and the applicant was told to come again when two other justices were present. Dr. Tinker does not refuse to carry out the law. These cases and others to which my attention is constantly being drawn illustrate the chronic friction which is caused by the present state of the law with regard to exemption certificates.

Medical Officer in Skye.

Mr. JOHN DEWAR asked the Secretary for Scotland whether he was aware that at Uig, in Skye, on the estate of the Congested Districts Board, there was no proper residence for the medical officer and that in consequence, there was difficulty in retaining the services of a doctor in the district; and whether he would use his influence with the Congested Districts Board to induce it to put one of the houses belonging to it in Uig at the disposal of the medical officer.—Mr. SINCLAIR answered: The responsibility of the Congested Districts Board in this matter is simply that of any other landlord in the district and at present I regret to say that there is no prospect of the Board being able to provide a house for this purpose, but I am aware that the difficulty in such cases is a real one. To enable the parish council by whom the doctor is employed to meet it legislation will be necessary and I will consider whether or not steps should be taken in this direction.

Medical Men and Vaccination.

Mr. LUPTON asked the President of the Local Government Board whether he would treat the publication by a qualified medical man of an opinion adverse to vaccination as a bar to his appointment as medical officer of health, as was done in the Penze district council case in April, 1901; and, if the answer be in the affirmative, whether he would state how he proposed to safeguard the free expression of scientific opinion by medical officers of health.—Mr. JOHN BURNS replied: I cannot give a general answer on the point referred to in the first part of the question. If it comes before me in any particular case I shall be prepared to consider it.

"Spotted Fever" in Glasgow.

Mr. CHARLES SCHWANN asked the President of the Local Government Board whether repeated cases of "spotted fever" had occurred for some months in Glasgow; and, if so, whether he would consider the desirability of requiring that the disease shall be placed on the list of those for compulsory notification, not merely in Glasgow but as a general order.—Mr. JOHN BURNS replied: The

Infectious Diseases (Notification) Acts do not empower the Local Government Board to issue a general order making a disease compulsorily notifiable, and I am advised that in present circumstances there would be no need for any such general order as regards the particular disease referred to in the question. With the approval of the Board, however, action for the purpose of making this disease notifiable may be taken by any sanitary authority in England and Wales (with which alone I am concerned) so far as relates to the district of the authority, and in August last the Board issued a circular to the several authorities stating that it would be prepared to consider an application for its approval to an extension of the Act to the disease should the sanitary authority desire, in view of any special circumstances, to make the necessary application. Some applications of the kind have since been made and approved.

TUESDAY, JULY 3RD.

False Descriptions of Brandy.

Mr. T. M. HEALY asked the Chancellor of the Exchequer whether he would state what precautions the Customs take to enforce the provisions of the Merchandise Marks Act as regards brandy; what check there is against the use of false trade descriptions; if any test is applied and what is it to ascertain whether spirit entered as brandy is derived from the grape or from materials other than the grape; how many gallons of spirit imported from Hamburg were admitted to entry last year as brandy; was such spirit the distillate of the grape; how many seizures were made last year of brandy to which a false trade description was applied under the Merchandise Marks Act; what was the quantity of brandy as per Customs entries from Norway, Holland, and Denmark for the last ten years; and is it the case that at London docks any spirit, whatever its origin, shipped as brandy is so entered by Customs and dock officials.—The CHANCELLOR OF THE EXCHEQUER replied: The means taken by the officers of Customs to prevent imported spirits being falsely described as brandy in contravention of the Merchandise Marks Acts are to examine all spirits entered as brandy and if such do not appear to be the brandy of commerce to submit samples to the departmental analyst. No test is applied to ascertain whether spirit entered as brandy is derived from the grape or from other materials but tests are applied to ascertain whether such spirits contain those constituents other than spirit which characterise the brandy of commerce. If such constituents are not present the spirit is not allowed to be entered as brandy. Particulars of the quantity of brandy imported from Hamburg are not available, the records of imports being shown under countries only. During the year 1905 two consignments of spirits described as brandy were seized under the Merchandise Marks Act, 1887, for having a false trade description applied. The quantity of brandy imported into the United Kingdom from Norway, Holland, and Denmark during the last ten years was as follows:—

Years.	Norway.	Netherlands.	Denmark.
	Proof gallons.	Proof gallons.	Proof gallons.
1896	3,032	34,012	9,481
1897	66	35,756	26,442
1898	2	22,066	11,142
1899	641	24,330	23,068
1900	6,363	22,446	2,824
1901	3,342	17,410	1,186
1902	3,184	14,521	1,688
1903	4,699	8,276	32
1904 { Imported ...	294	7,033	32
{ Consigned ...	292	3,564	32
1905 { Imported ...	1,928	5,947	61
{ Consigned ...	1,928	2,320	61

As will be seen from what is stated above it is not the case that at the London Docks or elsewhere any spirit, whatever its origin, shipped as brandy is allowed by the Customs Department to be entered as brandy. The Board has no official knowledge as to the action of the dock officials with regard to such spirits.

SELECT COMMITTEE ON JUVENILE SMOKING.

The Select Committee of the House of Lords, which was appointed, under the chairmanship of Earl BRUCE, to consider the Juvenile Smoking Bill introduced by Lord REAY and was further empowered to deal with the question of juvenile smoking generally and its effect on the physical condition of children, and to report whether any, and if so what, alterations in the law were desirable or practicable with a view of stopping the sale of tobacco and cigarettes to children below a certain age, commenced the hearing of evidence on June 26th.

Mr. BOWICK, treasurer of the Hygienic League, spoke in favour of the Bill, although he thought that the parent and the child should share the onus that was put upon the trader.

The Rev. B. S. LOWE, representing the R.E.D. Brotherhood, a movement aiming at the influencing of boys by other boys, gave evidence as to the sufficiency of moral suasion without legislative enactment.

Dr. WIGMORE, a member of the executive committee of the Hygienic League, stated that that organisation was in favour of legislation to prevent juvenile smoking and apparently there was a very strong parental opinion behind the movement. Boys were smoking a good deal more than they used to do and they were deteriorating in consequence. Girls were not deteriorating so much. After speaking of some of the physical effects of smoking he said he would propose that power should be given to flog boys under the Juvenile Offenders Act. The slot machines proved a temptation to youths and he would prohibit tobacco or cigarettes from being on sale in such machines.

Professor G. SIMS WOODHEAD of the University of Cambridge said that he had given attention to the subject and had studied the results of the experiments at Yale, and he was convinced that smoking did

interfere with the development of the growing child. There was a distinct difference in weight and chest measurement as between smokers and non-smokers. As to the immediate effect of smoking the nerve cells appeared to be slightly stimulated, but as soon as that condition passed off there was a distinct depressant action. Some other narcotics had very much the same action as nicotine which was one of the most harmful in general use. The nerve cells in the brain played a very important part in respiration, the action of the heart, and the functions of nutrition. The nicotine acted on the terminal nerves and they got alterations in the secretion of the mucous membrane. In addition to that the spinal cord seemed to be affected. Nicotine had the effect of interfering with the oxidation of the tissues. The mental activity of the child, owing to the depression of the nerve cells, was certainly impaired, as well as the desire for physical exercise. It was well known that tobacco, in the case of the adult, interfered with the function of the eye in regard to the perception of colour and the field of vision. They also found a structural change leading to amblyopia. One other effect was the throwing of extra work on the kidneys. Altogether he looked upon the action of tobacco on the child as very complicated. The cumulative results on the different parts of the body were very serious. Very minute quantities of nicotine had a very serious effect.

The CHAIRMAN: What quantity is there in a dozen ordinary packets of cigarettes?—Probably enough to poison if given all at once, or enough to produce very severe symptoms.

By Lord ABERDARE: He agreed with the opinion expressed by a well-known physician, which was alluded to in a circular issued by the Edinburgh School Board, to the effect that the cigarettes which boys chiefly used were rank poison.

Lord HENEGRE: Would you consider cigarette smoking a great deal more harmful to young people than common tobacco?—There is a difference in the way in which they are burned. In cigarette burning there is rather more perfect oxidation of the tobacco and therefore the effect is not the same as with the pipe but the paper products have probably a worse effect. As regards the combustion of the tobacco I do not believe it is quite so poisonous in the cigarette as in the pipe but the products of the paper are irritant and might have a rather serious effect.

The practical effect on the boy would be worse from the cigarette than from the pipe?—I should not like to commit myself to that.

Continuing, he said that he had taken the trouble to find out medical opinion and it was strongly against smoking by children. It was better for people not to smoke until after the age of 21 years. The public, he thought, would support very strong measures and he was generally in favour of the Bill. He did not think it was hard on the tradesman that the onus of proof of age should lie with him because the tradesman was giving tobacco to the child knowing that it would do harm.

By Lord ABERDARE: If this matter of juvenile smoking were not taken in hand the results in another generation might possibly be very serious.

By Lord HENEGRE: He did not think that the force of public opinion among the boys themselves would be sufficient to stop the vice.

Sir WILLIAM BROADBENT said that he agreed as to the desirability of preventing as far as possible smoking in early life.

The CHAIRMAN: The age of 16 or 17 has been suggested as a limit as well as 21?—I should prefer it to be 21 although the worst of the mischief is done before 16.

We are told that the general deterioration is not so observable amongst girls as amongst boys?—That is quite true.

Is one of the reasons smoking?—I should have no doubt that that entered into the causation.

As to the general results of juvenile smoking he had seen it affecting the circulation, the nervous system generally, and the digestion. As far as his personal experience went he saw more tobacco amblyopia among grown-up people than young people.

You do not think it causes cancer?—No, certainly not in the young. It is a very common cause of indigestion.

Drinking and smoking very often went together. Self-indulgence in one thing led to self-indulgence in another. Smoking excited thirst, lowered the general tone, and made a man much more ready to give way to the desire for stimulants. While he admitted that smoking entered into the causation of deterioration there were other factors more important, such as the want of ventilation, improper food, and the absence of exercise. These were more important, he thought, than the specific influence of smoking or self-abuse. Smoking weakened the heart and lowered the digestion generally. It rendered the heart more liable to disturbance and the digestion was affected. There was the serious matter of giving way to habits of self-indulgence and boys were led to concealment and to habits of deceit.

By Lord BIDDLEPH: The effects of smoking were not immediate; it was the establishment of the habit that was of serious importance.

By Lord HENEGRE: Smoking was doing a great deal of harm among adults and it was most desirable that there should be some prevention of juvenile smoking. Cigarettes did more harm than pipes because the smoke was often inhaled.

Mr. M. D. CHALMERS, Under Secretary of the Home Office, said that although every one was generally agreed that smoking was injurious to the young it would be satisfactory to all concerned if evidence of a specific nature were gathered. Medical men, perhaps, might give evidence as to specific cases of injury to young persons. He proceeded to criticise in some detail the provisions of the Bill.

Mr. J. L. PATON, high master of Manchester Grammar School, stated that the smoking habit tended to make boys selfish and deceitful. It also tended to reduce the will power and to make boys indolent and disinclined to take part in athletics. He suggested that power should be given to the elementary school teachers and to policemen and park officers to confiscate cigarettes seen in the possession of boys.

The Committee adjourned.

The Committee resumed the taking of evidence on June 29th.

Sir RALPH LITTLE, K.C., was the first witness. He stated that he was quite convinced that the smoking of cigarettes by young boys was ruinous to their physical well being and he would be glad to see the practice put down by legislative measures. He did not think that there would be any objection to give the police powers to search a lad if they thought that he had cigarettes on his person, or to take away his cigarettes if they found him smoking.

Dr. MACNAMARA, M.P., was also called as a witness. Examined by

the chairman he spoke of his objections to the habit of smoking cigarettes which prevailed amongst boys and immature youths. He was of opinion that the police should be invested with powers to take away cigarettes from boys when they found them smoking. One of the most objectionable and filthy forms of juvenile smoking, which in particular required checking was when a boy picked up the end of a cigarette from the gutter and began to puff it. This practice ought to attract the vigilance of the police. Although he would give the police power to confiscate the cigarette he did not think that they should inflict punishment on the juvenile offender on the spot. He did not agree that statutory powers should be given to members of the general public to take away cigarettes from boys, although he had admitted that he had done so himself. He knew that objection had been taken to the proposal to abolish the licence of a tobacco seller after his third conviction for supplying juveniles with cigarettes, but he did not know if that would meet the case. In the matter of penalties the Bill might be a little drastic. However, the magistrate might have power to take away a tobaccoist's licence if he sold cigarettes to boys after repeated convictions and ineffectual warnings.

THE CHAIRMAN: On the general question of physical deterioration we have been told that it has not been so marked amongst girls as amongst boys. Would you agree, after the evidence that has come before you, that this was the case?

DR. MACNAMARA: I should think it is so. The facilities for the physical training of girls, he proceeded to say, had enormously improved in the last ten years in schools, both elementary and secondary. He should say that the average girl now got as good a physical training as her brother if not a better one.

THE CHAIRMAN: We have been told that one reason of physical deterioration amongst boys is that they smoke so much.

DR. MACNAMARA: I have certainly been very much struck by the increase of smoking cigarettes amongst boys. When I was a schoolmaster in 1882 there was practically no cigarette smoking at all amongst them. The whole thing had developed in the last ten years. It was still rapidly developing. As to the deteriorating effects the committee has had evidence showing the effect of it upon the nerves, the heart, and the eyes in the case of unformed youths. It was the case, unfortunately, that tobacco-sellers had recently laid themselves out very much to cater for children.

At this point **DR. MACNAMARA** produced a packet of cigarettes which, he said, were specially designed for children and which he handed to the Chairman for examination. Witness proceeded to say that this packet containing five cigarettes was sold for 1d. and the shopkeeper also provided a small box of matches and a clay cigarette holder. It was perfectly obvious that the tobacco in cigarettes at five for 1d. could not be of a superior quality. Any of their lordships could test the quality of these cigarettes for himself. He thought it would be wise to adopt a clause in the Bill similar to the messenger clause in the Sale of Intoxicating Liquors to Children Act.

MR. W. TODD, secretary to the Scottish Anti-Tobacco Society, Edinburgh, having expressed himself strongly in favour of legislation to put down cigarette smoking amongst boys, handed to the committee excerpts from **THE LANCET** in support of his contentions.

MR. LENNIE, Secretary to the Sweetmeats Automatic Delivery Company, made a statement to the effect that the withdrawal of cigarettes from sale in the machines of his company at railway stations would be ruinous to it financially. The cigarettes in these automatic delivery machines were sold at the rate of two a 1d. and he did not think that they constituted a great temptation to boys. The cessation of this traffic in cigarettes would be a hardship to the travelling public.

MR. JOHN KIRK, Secretary to the Ragged School Union, in his evidence told the committee that he knew of many cases where boys went without food in order that they might be able to purchase cigarettes. He advocated speedy legislation to cope with the evil.

MR. A. P. SAUNDERS of Stafford stated that from his experience as a schoolmaster he could pick out the boys in a school who were suffering from tobacco heart by the flabby character of their handwriting.

MR. W. R. DANIEL, speaking on behalf of the Wholesale Tobaccoists Protection Association, claimed that the trader should be entirely exempt from penalties in connexion with the selling of cigarettes. The entire responsibility for juvenile smoking should rest on the boy as culprit and on the police as prosecutors. He did not think that juvenile smoking was on the increase.

The Committee adjourned.

The Select Committee heard further evidence on July 3rd, **EARL BRANCHAMP** being in the chair.

MR. JOHN LINDSAY, solicitor and town clerk depute of Glasgow, gave evidence with respect to the steps which had been taken during the last two years by the corporation of Glasgow and the school board of Glasgow with the aim of obtaining legislation to put down juvenile smoking. Widespread support was given to the efforts of the corporation by other Scottish municipalities and deputations representing many Scottish local authorities and organisations had on two occasions waited upon the Lord Advocate of the day to press their views against juvenile smoking. On the occasion of the last deputation in the spring of this year the public bodies represented at it were, with the qualified exception of the Glasgow school board, quite satisfied with the provisions contained in **DR. MACNAMARA'S** Bill for the Prevention of Juvenile Smoking. They felt convinced that if a law were passed prohibiting dealers in tobacco from selling or supplying the same to children under the age of 16 years a great deal of the evil affecting the tobacco habit would be arrested. The school board of Glasgow thought that a penalty clause should be provided in the case of children, but they admitted that the provisions of the Bill would be beneficial. The most progressive municipalities in Scotland were in favour of legislation against juvenile smoking.

MR. E. F. GASTON (London), manager of Messrs. Funk and Wagnalls, publishers, gave evidence with respect to the legislation in existence in the United States of America for the prevention of juvenile smoking. The first legislation took place in 1883 and now 47 out of the 53 States and territories had enactments on the subject. The cigarette was an acute issue in America because of the cheap tobacco which was ordinarily employed in making it and because of the dirty surroundings in which the tobacco was gathered and made up and also the amount of drugging which it underwent. Speaking roughly, cocaine and laudanum were amongst the drugs which were used.

THE CHAIRMAN: What is the object of these drugs? Is it to make the taste better or to disguise the materials of which the cigarette is made?

WITNESS: By the use of some of the drugs the sense is peculiarly numbed and they act as a sedative immediately the cigarette is applied to the lips. Proceeding he said that the trend of American sentiment was that there should be some penalty on the parent who permitted his children to use tobacco. The general effect of the laws against juvenile smoking in America had been good. The American cigarette was the worst thing which the United States sent to this country—worse than Chicago tinned meat. In his opinion this country should enact strict legislation against the bad cigarette specially imported from the United States.

This concluded the evidence and the committee then sat in private to give consideration to Lord Reay's Bill.

BOOKS, ETC., RECEIVED.

BRUYLLANT, EMILE, 67, Rue de la Régence, Bruxelles. (OCTAVE DOIN, 8, Place de l'Odéon, Paris.)

Anatomie Clinique et Technique Opératoire. Par le Dr. O. Laurent, Professeur de Médecine opératoire à l'Université de Bruxelles, Chirurgien des Hôpitaux de Bruxelles. Price not stated.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

FOSS, EDWIN VINCENT, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 9 District by the Bristol Board of Guardians.

FRESHNEY, R., M.B. Syd., has been appointed Government Medical Officer for Toowoomba, and Official Visitor to the Westbrook Reformatory, Queensland, Australia.

GRAY, A. M. H., M.D., B.S. Lond., has been appointed Resident Medical Officer at University College Hospital.

MCDONNELL, ENEAS J., M.D. Syd., has been appointed Senior Honorary Surgeon to Toowoomba Hospital, Queensland, Australia.

ODGERS, N. B., M.B., M.Ch. Oxon., F.R.C.S. Eng., has been appointed Assistant Surgeon to the General Hospital, Northampton.

RANSAY, A., M.B., M.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Leadhills and Wanlockhead District of the counties of Lanark and Dumfries.

RING, C. A. E., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed District Medical Officer by the Okehampton (Devon) Board of Guardians; also Certifying Surgeon under the Factory and Workshop Act for the Hatherleigh District of the county of Devon.

ROSE, FRANK A., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Surgeon to the Ear and Throat Department with Charge of Out-patients at the Great Northern Central Hospital.

SMITH, S. MAYNARD, M.B., B.S. Lond., F.R.C.S. Eng., has been appointed Surgeon in Charge of Out-patients at St. Mary's Hospital.

SUTHERLAND, J. R., M.B., Ch.B. Glasg., has been appointed Junior House Surgeon at the Blackburn and East Lancashire Infirmary.

WILSON, A. GARRICK, M.B., M.C. Cantab., F.R.C.S. Eng., has been appointed Surgeon to the Sheffield Children's Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.

BRIGHTON THROAT AND EAR HOSPITAL, Church-street, Queen's-road.—Non-resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

BURNLEY, VICTORIA HOSPITAL.—Resident Medical Officer. Salary £100, with residence, board, and washing.

CANCER HOSPITAL, Fulham-road, London, S.W.—Medical Officer in Charge of Electrical Department. Honorarium £25 5s. per annum.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road.—Assistant Surgeon. Also Third Assistant Anaesthetist.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, residence, &c.

DERBY, DERBYSHIRE ROYAL INFIRMARY.—Assistant House Surgeon for six months. Salary £30, with board, residence, and washing.

EGYPTIAN GOVERNMENT, MINISTRY OF EDUCATION.—Professor of Midwifery and Gynaecology. Salary £400 a year. Also Medical Tutor and Registrar to Kas-el-Ainy Hospital. Salary £400 a year.

GLOUCESTER GENERAL INFIRMARY AND GLOUCESTERSHIRE EYE INSTITUTION.—Assistant House Surgeon. Salary at rate of £30 per annum, with board, residence, and washing.

GREAT NORTHERN CENTRAL HOSPITAL.—Ophthalmic Surgeon.

HARTLEPOOLS HOSPITAL.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—Assistant House Surgeon for six months. Honorarium £20, with residence, board, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £20, with board and residence. Also Assistant Casualty Medical Officer, unmarried, for six months. Salary £20, with board and residence, &c. Also Radiographer.

HOSPITAL FOR WOMEN, Soho-square, W.—Medical Registrar. Honorarium 25 guineas.

HULL, ROYAL INFIRMARY.—Casualty House Surgeon. Salary £50 per annum, with board and lodging.

LIVERPOOL STANLEY HOSPITAL.—Lady Honorary Medical Officer for Women's Diseases.

MANCHESTER, CHORLTON-UPON-MEDLOCK DISPENSARY.—Resident House Surgeon, unmarried. Salary £120 per annum, with rooms and attendance.

MANCHESTER, UNIVERSITY OF.—Junior Demonstrator in Physiology. Salary £100, rising to £150 per annum.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Surgeon and Assistant Surgeon.

OXFORD, LITTLEMORE PAUPER LUNATIC ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, with rooms and board.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Assistant House Surgeon for six months, renewable. Salary at rate of £50 per annum, with board, residence, and washing.

ROYAL DENTAL HOSPITAL OF LONDON.—Demonstrator in Mechanical Pupils' Department. Salary £120, rising to £150.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £50 per annum, with board and lodging.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at rate of £40 per annum, with board, washing, and residence.

WANDSWORTH UNION INFIRMARY, St. John's-hill, near Clapham Junction.—Junior Assistant Medical Officer, for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House Surgeon. Salary £70 per annum, with rooms, board, and washing.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Whaley Bridge, in the county of Chester, and at Standrop, in the county of Durham.

Births, Marriages, and Deaths.

BIRTHS.

BENNETT.—On June 28th, at Hillcrest, Northwood, the wife of Norman G. Bennett, M.A., M.B., B.C., L.D.S., of a daughter.

BYRE.—On June 7th, at Holmsdale, Wandsworth Common, to Dr. and Mrs. Byre, a son.

GORDON-WILSON.—On July 1st, at Philbeach-gardens, South Kensington, the wife of Dr. A. Gordon-Wilson, of a son.

HANCOCK.—On June 28th, at Escott, Streatham, the wife of W. Ilbert Hancock, F.R.C.S., of a son.

HAY.—On July 2nd, at Lincoln-road, Peterborough, the wife of William Pesch Hay, M.B. and C.M., of a daughter.

JOHNSON.—On June 29th, at Ellerker-gate, Richmond-hill, Surrey, the wife of John Robert Johnson, M.R.C.S., L.R.C.P., of a daughter.

PARK.—On June 26th, at Knighton, Radnor, the wife of Wm. Norris Park, M.B., of a daughter.

MARRIAGES.

LERMING—LAMPREY.—On June 28th, at Wandsworth Common, Arnold Leeming, M.B., B.S. Lond., M.R.C.S., L.R.C.P., of Sudbury, Suffolk, elder son of Joseph Leeming, F.R.I.B.A., to Annie Maud, elder daughter of Charles Lamprey, Westwood Tower, Wandsworth Common.

ROOKE—GOODMAN.—On June 27th, at Christ Church, Guildford, W. Stanley Rooke, M.R.C.S., L.R.C.P., of Fairfield, North Finchley, to Elsie May, eldest daughter of Sir William Goodman, of Clavadel, Guildford, late Chief Justice of Hong-Kong.

STAFFORD—NIBLOCK.—On June 27th, at St. Michael's Church, Bournemouth, A. M. Stafford, M.B., to Miss Mary Niblock, daughter of the late Mr. J. Niblock.

STOCKWELL—COSTIGAN.—On July 3rd, at the Parish Church, St. Marylebone, G. E. St. Clair Stockwell, M.B., B.C. Cantab., to Gertrude Frances, second daughter of the late Thomas Costigan, Esq., of Birmingham.

WHARTON—ORME.—On June 28th, at the Baptist Church, King-street, Oldham, Alwyn Wharton, M.B., Ch.B., to Katie, only daughter of Daniel Orme, Wellington House, Oldham.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A POINT IN POOR-LAW.

A CORRESPONDENT recently asked us: "Am I as a Poor-law medical officer to attend paupers removed to an isolation hospital (not under the control of the guardians) by order of my relieving officer, such hospital being situated in my district?" The point is an interesting one and others of our readers may have been in a similar difficulty. There is no option in the matter if the isolation hospital is situated within his district and has no special medical officer appointed to attend to the inmates; the Poor-law medical officer must attend. The only remedy a Poor-law medical officer has when improperly directed by a relieving officer to attend a patient is to bring the matter before the guardians at their next meeting, but in the meantime he should obey the order. Of course, where a pauper has been sent into an institution where there is a medical officer appointed to take charge of all the inmates, then a Poor-law medical officer might be justified in disobeying an order to attend a pauper there, but the honorary secretary of the Poor-law Medical Officers' Association, Dr. Major Greenwood, informs us that he has never known an instance of an order of attendance being given in such circumstances. Where the medical officer of health has charge of an isolation hospital and is specially appointed with such a charge he should receive a special stipend for extra work, as it does not necessarily belong to his duties.

SIGHT DEFECTS AMONGST THE GENERAL POPULATION.

To the Editors of THE LANCET.

SIRS,—May I ask if any of your readers will furnish me with information bearing on the following subject? Are there any available statistics, reliable and ample, relative to the increase and prevalence of eye defects amongst the general population of this country other than those recently issued by certain of the local educational authorities? In asking for this information I do not refer to the statistics obtainable at the several eye hospitals, as obviously these relate only to the patients of these institutions and do not, except indirectly, affect the subject of the conditions of eyesight deficiency amongst the general population. Further, may I ask where, if at all, I can obtain similar information relative to the general population of the United States?

I am, Sirs, yours faithfully,

London, June 28th, 1906.

VIATOR.

PRESTON'S WATER WITH A FISHY SMELL.

COMPLAINTS of the water-supply of Preston having a fishy smell led to a discussion at a council meeting on June 29th. One member thought that the smell attributed to the Grimsargh reservoir really came from "a neighbouring sewage works." The reservoir and the sewage works do not seem well-assorted neighbours. Another gentleman thought that there were too many fish in the reservoir, while a third did not think that any number of fish would affect the water. He thought that the smell was due to the great numbers of shell-fish and had heard of cases where fish had been put in to preserve the purity of the water. Dr. Brown, chairman of the health committee, thought that the "dead ends" of the pipes were the source of the trouble. As bearing on this question there may be recalled a similar complaint made several years ago of the fishy smell of the water in some of the Manchester reservoirs. It happened fortunately that Mr. Estcourt, the chemist of the corporation, was also a fisherman. The reservoir was full of small water-snails but contained no fish to keep down their numbers and he advised the introduction of trout. In a short time the nuisance subsided and has not recurred. In all probability the same explanation and the same remedy, as suggested by one of the members, will be found applicable.

THE LEGISLATURE AND VIVISECTION.

A WRITER above the signature "Canny Scot" takes in the columns of the *Tribune* shrewd vengeance upon Mr. A. Lupton, M.P., who recently informed the readers of that excellent paper that "everybody now knows what the word vivisection means and what the practice is." "Canny Scot" proves that Mr. Lupton, at any rate, has no share in this general knowledge. "I do not know," writes "Canny Scot," "why Mr. Lupton should apply the contemptuous word 'clique' to vivisectioners, for they are in no way banded together; they form no offensive or defensive associations; they hold no exclusive meetings; they conduct no political propaganda; in fact, they have no interest to serve save the furtherance of the knowledge of disease and how best to combat it—surely a sufficiently high aim to save them from ungenerous detractors. Mr. Lupton may be able in the future to supply us with a little from his store of knowledge of the 'abhorrent practice'; at the present time, where his facts are not wrong, his conclusions are illogical. It is not essential, as he says, for a student studying for the London M.D. ever to witness a single experiment on any animal coming within the scope of the Vivisection Acts; it is not essential for him to perform any such experiments; and he is never asked by an examiner to perform a vivisection experiment during the examination, for such a

thing would be illegal. Mr. Lupton talks about vivisection holding important salaried posts. I hope he does not mean to insinuate that the salary is important. May I tell him a little secret? If he were to take the average salary of British vivisectioners he would probably find that in comparison his Chinese labourer on the Rand was living in a compound affluent paradise." "Canny Scot" then points out that the facts that in 1876 there were 23 vivisectioners and in 1904 366 do not prove that the law has encouraged men to engage in the practice. "I suppose," he says, "there are more motor-cars in use this year than there were three years ago, but I am sure the increase is not due to the issuing of licences. Within the last 30 years the modern advance in medicine has taken place; surgery has almost wholly changed during that time, while bacteriology and pathology in general have grown from comparative nothingness. To these he may attribute the increase in vivisection experiments." Alas, it is more than probable that the good humour and good sense of the corrections will be passed by unheeded by Mr. Lupton.

A POINT IN POOR-LAW.

To the Editors of THE LANCET.

SIRS,—Is not a workhouse medical officer entitled to £2 for instrumental midwifery in a difficult case of childbirth and entailing considerable attendance afterwards? I know a medical officer of a workhouse who always is paid that fee. A district medical officer always gets it. I am told it is always paid in London to workhouse medical officers. I am, Sirs, yours faithfully,

July 2nd, 1906.

M.P.

UNMANNERLY.

To the Editors of THE LANCET.

SIRS,—The following incident is, I hope, unique. I was rung up by A, a patient, who employs a large number of men, and told that one, B, who is a foreman in A's establishment, was very ill—he was, in fact, said to be almost in *extremis*. I was asked if I would kindly see B on A's behalf and let him (A) know whether anything could be done to relieve or to help him. A also asked what was the "etiquette" in such a case; Dr. D was attending B. I replied that Dr. D must be approached and should be told that Mr. A, the employer of B, would be glad if Dr. D would meet Mr. A's own medical attendant, Dr. C—i.e., the present writer—in consultation. This would show Dr. D, I suggested, that Mr. A desired to be peculiarly responsible for the whole business. Mr. A accordingly sent his son and partner on this errand and promised to let me know later what time Dr. D had fixed for consultation. I was astonished later to receive the following statement from Mr. A's son. He had seen Dr. D. Dr. D was annoyed and had asked who was Dr. C. He was told that he was another general practitioner living some two and a half miles away. Dr. D then flatly refused to see anyone else in consultation. He asserted that he was as good as any other general practitioner—a fact that was not in issue—and that he was not going to surrender his patient to any other man's treatment. Pressed further, he said that he would meet Dr. E, a consultant, but no one else. And there, so far as I was concerned, the matter ended. I was naturally rather vexed at receiving such a singularly uncivilised message through the agency of my own patient, although Mr. A took the trouble to state very plainly what he thought of Dr. D. What should I do? Personally I think I had better do nothing. I might add as facts relevant to the issue that Dr. D is L.R.C.S., L.R.C.P. Edin., while as you will see by reference to the Directory, I am certainly on the staff of a hospital. I inclose my card, and am,

Yours faithfully,

June 26th, 1906.

M.D. Lond.

. We agree with our correspondent that he should do nothing. The story as it is told reflects badly on Mr. D.—Ed. L.

ST. LUKE'S HOME FOR THE DYING POOR.

At a drawing-room meeting on behalf of this charity recently held by permission of Mrs. R. W. Perks at Kensington Palace Gardens, statements were made by Mr. A. Pearce Gould and Mr. Howard Barrett to show that the safety and protection of public health might consist in the multiplication of such homes. The majority of the patients seeking refuge were suffering from pulmonary tuberculosis or cancer and in regard to the first of these, at any rate, the cause of public health is served by removing sources of infection from crowded centres. Mr. Arnold White, who took the chair, commented on the fact that even the most debased savage crept away into some quiet corner to die and maintained that the natural instinct for privacy and dignity in dying was denied to our poor at home. The meeting was a cordial one and some substantial promises of assistance were received from the guests. The patroness of the charity is Her Majesty the Queen and full particulars will be gladly given by the honorary secretary, Miss Helen E. Don, St. Luke's House, 14, Pembridge-square, Bayswater, W.

Spec.—The regulations differ in different States. If our correspondent will send in his name and the date of his diplomas, and will also indicate the State in which he intends to practise, we may be able to tell him what he wants to know.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (9th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (3 P.M.).

TUESDAY (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.).

WEDNESDAY (11th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopaedic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.).

THURSDAY (12th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopaedic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.).

FRIDAY (13th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopaedic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), St. Mark's (2.30 P.M.).

SATURDAY (14th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (10th).—SOCIETY FOR THE STUDY OF INEBRIETY (11, Chandos-street, Cavendish-square, W.).—3.30 P.M.: Council Meeting. 4 P.M.: Discussion on the Relations of Inebriety and Crime (opened by the Rev. Canon J. W. Horsley).

WEDNESDAY (11th).—DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—5.15 P.M.: Meeting.

THURSDAY (12th).—BRITISH GYNAECOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M.: Specimens will be shown by Dr. Macnaughton-Jones, Dr. J. Aarons, and Dr. C. Maunsell. Papers:—Dr. J. Oliver: A Study of Hydatidiform Mole, with Records of Three Typical Cases.—Dr. Macnaughton-Jones: Remarks on Closure of Small Recto-vaginal Fistula involving the Sphincter.

FRIDAY (13th).—OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos-street, Cavendish-square, W.).—8 P.M.: Card Specimens. 8.30 P.M.: Papers:—Mr. W. T. H. Spicer: Intraocular Infections.—Mr. A. H. Bralley: Congenital Diasthesis.—Mr. C. H. Usher (Aberdeen): A Note on the Choroid at the Macular Region. Annual General Meeting. Election of Officers for 1906-07.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (9th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Dr. J. Galloway: Clinique. (Skin) 5.15 P.M.: Lecture.—Mr. B. Harman: Biepharitis. POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Diseases of the Eye. 5 P.M.: Lecture.—Mr. Dunn: Ocular Diseases of Childhood.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Sir D. Duckworth: Medicine. 3.15 P.M.: Mr. W. Turner: Surgery. 4 P.M.: Dr. St. Clair Thomson: Throat and Ear. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat.

CHARING CROSS HOSPITAL.—4 P.M.: Dr. Routh: Demonstration (Gynaecological). (Post-Graduate Course.)

TUESDAY (10th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Dr. T. Williams: Clinique. (Medical.) 6.15 P.M.: Lecture.—Dr. L. Smith: Some Points in the Treatment of Epilepsy.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. Diseases of the Throat, Nose, and Ear. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Diseases of the Skin. 5 P.M.: Lecture: Dr. Moullin: Retroflexion, Symptoms and Treatment.
 LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. E. T. Hewlett: Medicine. 3.15 P.M.: Mr. Carless: Surgery. 4 P.M.: Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Skin.
 NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Dr. A. Turner: Speech Defects.

WEDNESDAY (11th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Mr. T. P. Legg: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Dr. C. O. Hawthorne. Pulse Tracings and their Clinical Significance.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Diseases of the Throat, Nose, and Ear. Diseases of Children. 2 P.M.: Medical and Surgical Clinics. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. 5 P.M.: Lecture:—Dr. Beddard: Practical Medicine.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. F. Taylor: Medicine. 3.15 P.M.: Mr. M. Robson: Surgery. 4 P.M.: Mr. Cargill: Ophthalmology. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M.: Demonstration:—Dr. Abercrombie: Nose.

THURSDAY (12th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Mr. H. S. Clogg: Peritonitis in Children.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Diseases of the Eye. 5 P.M.: Lecture:—Mr. Baldwin: Practical Surgery.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. G. Rankin: Medicine. 3.15 P.M.: Sir W. Bennett: Surgery. 4 P.M.: Mr. M. Davidson: Radiography. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Ear and Throat.

HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M.: Lecture:—Dr. Thursfield: Secondary Anemias in Children.

FRIDAY (13th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.).—4 P.M.: Mr. E. Clarke: Clinique. (Eye.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M.: Medical and Surgical Clinics. Diseases of the Throat, Nose, and Ear. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Diseases of the Skin. 5 P.M.: Lecture:—Mr. Lloyd: Anesthetics and their Administration.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. 2.30 P.M.: Dr. R. Bradford: Medicine. 3.15 P.M.: Mr. McGavin: Surgery. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 12 noon: Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M.: Clinical Lecture:—Mr. Ballance: Surgery of the Nervous System.

SATURDAY (14th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M.: Diseases of the Throat, Nose, and Ear. 2 P.M.: Medical and Surgical Clinics. 2.15 P.M.: X Rays. 2.30 P.M.: Operations.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M.: Operations. Out-patient Demonstrations.—10 A.M.: Surgical and Medical. 11 A.M.: Eye.

EDITORIAL NOTICES.

It is most important that communications relating to the editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol. I. of 1906, which was completed with the issue of June 30th, and the Title-page to the Volume, are given in this number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1906 will be ready shortly. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Stewart's Instruments.)

During the week marked copies of the following newspapers have been received:—Manchester Chronicle, Plymouth Eastern Morning News, Cork Constitution, Standard, Birmingham Daily Mail, Daily Chronicle, Malvern Gazette, Scarborough Mercury, Hackney Mercury, Morning Leader, Daily News, Daily Telegraph, Islington News, Birkenhead Advertiser, Manchester City News, Kettering Leader, Derbyshire Courier, Islington Gazette, &c.

Communications, Letters, &c., have been received from—

A.—Mr. F. H. Allen, Sheffield; Dr. B. Anningson, Cambridge; Ammonol Chemical Company, New York; Dr. A. B. Ash, Hontion.

B.—Mr. C. Birchall, Liverpool; Messrs. Battle and Co., Paris; Mr. T. B. Browne, Lond.; Mr. A. S. Bassler, San Francisco, U.S.A.; Mr. T. Bates, Worcester; Mr. W. Bryce, Edinburgh; Mr. J. A. Barth, Leipzig; Bayer Co., Lond.; Bureau Communal de Statistique et la Bibliothèque de la Ville de Budapest; Dr. F. G. Bushnell, Brighton; Dr. W. Blair Bell, Liverpool; Mr. Haydn Brown, Caterham; Messrs. Burroughs Wellcome and Co., Lond.; Bradford Royal Infirmary, Secretary of; Messrs. C. Barker and Sons, Lond.; Mr. C. A. G. Browne, Lond.; Mr. A. Benthall, Lond.; Mr. Andrew Brodrick, Lytham.

C.—Mr. G. W. Clark, Plymouth; Colonial Secretary, Hong-Kong; Messrs. T. Christy and Co., Lond.; Mr. A. M. Cato, Lond.; Mr. G. M. Cabrera, Lond.; Consulado General del Uruguay en la Gran Bretaña, Lond.; Messrs. Samson Clark and Co., Lond.; Central London Throat and Ear Hospital, Secretary of; Dr. George Carpenter, Lond.

D.—Dr. T. Domela, Tunis; Derbyshire Royal Infirmary, Derby, Secretary of; Dermatological Society of Great Britain and Ireland, Lond.; Joint Hon. Secretary of; Dewver Chemical Manufacturing Co., New York; Mr. J. W. Dryland, Kettering.

E.—Messrs. Evans, Sons, Lescher, and Webb, Lond.; The Misses Erwin, Lond.; Dr. G. H. Evans, San Francisco, U.S.A.

F.—Dr. J. D. Farquharson, Newcastle-on-Tyne; F. R. W., Lond.; Messrs. Fairchild Bros. and Foster, Lond.

G.—Mr. G. Gronauer, Memphis, Tennessee, U.S.A.; Gloucester General Infirmary, Secretary of; Guy's Hospital, Lond.; Governors and Medical Staff of; Mr. F. H. Godsell, Lond.; G. F.; Dr. G. A. Gibson, Manchester.

H.—Messrs. J. Haddon and Co., Lond.; Mr. P. Harper, Lond.; Hastings, St. Leonards, &c., Hospital, Secretary of; Hong-Kong, Principal Civil Medical Officer of; Mr. Frederic Harrison, Hawkhurst; Hartlepool Hospital, Secretary of; Messrs. Hendry and Pattison, Lond.; Hull Royal Infirmary, Secretary of; Hotel Tariff Bureau, Lond.; Captain J. Houston, Lond.; Dr. George H. Hume, Newcastle-on-Tyne.

J.—Dr. W. H. Jamison, Lond.; Dr. Robert Jones, Claybury; Dr. John's Sanatorium, Park-

stone, Secretary of; J. A. B.; Joyce Sanitary Compounds Co., Lond.; J. H. M., Lond.

K.—Dr. Charles Kerr, Dundee; Messrs. J. Keele and Co., Lond.; Messrs. R. A. Knight and Co., Lond.; Mr. A. Keith, Lond.

L.—Mr. Oliver Leigh, Chicago; Local Government Board, Dublin, Secretary of; League of Mercy, Lond.; Leeds University, Registrar of; Mr. H. K. Lewis, Lond.; Littlemore Asylum, Oxford, Clerk to the; Mr. Cecil H. Leaf, Lond.

M.—Dr. R. O. Macfie, Dunblane; Medical Society of Victoria, Melbourne, Hon. Secretary of; Messrs. Maconochie Bros., Lond.; Messrs. Maple and Co., Lond.; Mr. W. Murray, Lond.; Messrs. O. Mitchell and Co., Lond.; Maitine Manufacturing Co., Lond.; Mr. R. Mosse, Berlin; Dr. George Marr, Knysna, Cape Colony; Mr. John Murray, Lond.; Dr. Hector Mackenzie, Lond.; M. T. T.; Medico-Legal Society, New York, President of.

N.—Mr. J. C. Needes, Lond.; Mr. H. Needes, Lond.

O.—Dr. Thomas Oliver, Newcastle-upon-Tyne.

P.—Dr. J. S. Purdy, Port Said, Plymouth Borough Asylum, Blackadon, Medical Superintendent of; Dr. Planer, Dresden; Mr. H. G. Plimmer, Lond.; Mr. E. H. Parker, Liverpool; Messrs. Peacock and Hadley, Lond.; Fleet-Surgeon A. M. Page, R.N., Plymouth; Patent Aëdon Flour Co., Ramsgate; Dr. Frank Penrose, Lond.

R.—Dr. W. Robinson, Sunderland; Mr. R. Redpath, Newcastle-on-Tyne; Rebman, Ltd., Lond.; Royal National Hospital for Consumption for Ireland, Dublin, Secretary of; Royal Sanitary Institute, Lond., Secretary of; Dr. Philip Rees, Canton; Mr. Fred Reynolds, Leeds; Radcliffe Infirmary, Oxford, Secretary of; Dr. A. E. Russell, Lond.; Royal Albert Asylum, Lancaster, Secretary of; Messrs. A. Reid and Co., Newcastle-on-Tyne.

S.—Dr. J. P. Steele, Birkdale; Messrs. Henry Schluter and Co., Lond.; Mr. H. C. Scott, Lond.; Dr. G. F. Darwall Smith, Lond.; Messrs. Spiers and Pond, Lond.; Dr. Ed. Schloesser, Allevard-les-Bains; Messrs. Smith, Elder, and Co., Lond.; Sheffield Royal Hospital, Secretary of; Southern Medical Agency, Hove; Messrs. G. Street and Co., Lond.; St. Andrew's Hospital, Northampton; Saarbach's News Exchange, Mainz; Salford Royal Hospital, Secretary of; Dr. F. Shuffebotham, Newcastle-under-Lyme; Dr. R. A. Stoney, Dublin; Professor E. H. Starling, Lond.;

Dr. J. W. Stenhouse Old Trafford; Dr. H. W. Syers, Lond.; Dr. John Stokes, Sheffield; Mr. K. Schall, Lond.; Dr. A. W. Scott, Woodhouse.

T.—Dr. J. C. Thrush, Chelmsford; Messrs. S. W. Thompson and Co., Lond.; T. J. C.

V.—Victoria Hospital, Burnley, Secretary of; Mr. N. J. F.

Vazifdar, Bombay; Mr. C. J. Van Bijn, Cape Town.

W.—Professor G. Sims Woodhead, Cambridge; West Bromwich District Hospital, Secretary of; Messrs. A. J. Wilson and Co., Lond.; Mr. W. A. M. Wakeman, Adis Ababa; Dr. T. R. Whigham, Lond.; Messrs. Wyleys, Ltd., Coventry.

Letters, each with enclosure, are also acknowledged from—

A.—Dr. C. T. Andrew, Lond.; Apollinaris Co., Lond.; A. E. J.; Messrs. Armour and Co., Lond.; A. B. C. Lond.; A. S. M.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an additional advertisement.
 Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.
 The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.
 Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.
 THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, Rue Bapts, Asnières, Paris.

Lecture

OR

DENDRITES AND DISEASE.

*Delivered at the National Hospital for the Paralyzed and Epileptic,*BY SIR WILLIAM R. GOWERS, M.D. LOND.,
F.R.S.,PHYSICIAN TO THE HOSPITAL; CONSULTING PHYSICIAN TO UNIVERSITY
COLLEGE HOSPITAL.

GENTLEMEN,—If a theory explains many facts otherwise obscure it is not thereby proved to be true. This effect has small weight if the theory has no other support, but if it rests on carefully observed facts the circumstance that it harmonises and elucidates does increase the probability that it is true. Sometimes, therefore, it is worth while to consider this effect alone, if we are careful not to mistake it for proof or give more weight to it than is just. It does the service, also, of directing attention to the more important features of the problems concerned.

You know the change in our ideas of the central nervous system that is implied in the word "neuron." Some of you, indeed, may not know it as a change because you have learned nothing else, the changed conception being now treated as current knowledge. Yet its full significance is still imperfectly discerned and its influence on our conceptions of functional disease of the nervous system has obtained hardly any recognition. This is so great and so elucidating that it merits careful consideration. In trying to point out what influence on our ideas the neuron theory should have I must assume it as a demonstrated fact. There is still some difference of opinion regarding its full details, but the leading facts are stated as our present knowledge in the modern text-books of physiology. Taking them as such, my object now is to consider what influence they should have on our conceptions of the action of the nervous system, especially in its perverted forms.

Before considering this I must take care that you have the leading facts clearly in your mind. It is never safe to assume knowledge. So I will remind you of them, without burdening you with the names of the workers to whom we owe them. These are indeed well known and only the essential points that have been established really concern us. For the new knowledge we are indebted to histologists; their importance to us depends on the change in physiological thought they compel. Physiology is the science of life but we hardly realise to what a vast extent it is dependent on the labours of the anatomist simple and minute. The lessons of simpler structure have long been learned. The limits of microscopic vision are nearly reached, but the power of chemistry has been invoked as a differentiating aid to distinction and discernment, and it is entirely to this that we owe the new knowledge which concerns us to-day.

It was formerly thought that there was a continuity of conducting paths through all the complex structures of the central nervous system, that through the cells and fibres there was no break. It is now held that each "neuron"—that is, each cell with the processes and fibres that spring from it—is separate from every other. The terminal branchings of the processes do not unite; they end in contiguity to others, not in continuity with them. Instead of simple conduction from one to another throughout the nerve centres, brain, and spinal cord, there is a break between the elements; it may be minute but it has to be crossed and the crossing apparently involves a break in the process. Instead of the nerve impulse passing on unchanged when it reaches the termination of the neuron which has brought it, it *excites* an impulse in the adjacent neuron. A process of excitation is essentially different from conduction. That which is excited depends more on the structure in which it is produced than on the stimulus that acts on it. A slight exciting impulse may cause an energetic effect in the structure on which it acts. We can thus understand better the fact that a touch on the sole may excite an energetic movement of the leg. Not only may the energy excited be

vastly greater than that which excites but the latter may act on the endings of many neurons. Thus the apparent conduction through the nerve centres is really by a succession of neuron impulses.

Where is it assumed that the break occurs and the simple conduction through one neuron becomes a process of stimulation of the next? To answer the question we must consider the facts of structure. Each cell has, besides its long nerve-fibre process (the axon), other processes quickly branching and apparently disappearing in the almost homogeneous-looking substance in which the nerve cells lie and in which are also the minute blood-vessels. I have called it the "matrix" as an indifferent term. For the same reason it has been called "the grey." These branching processes were formerly thought to consist of protoplasm and to be concerned only with the nutrition of the cells. Better means of observation have revealed the fact that they consist of fine nerve fibrils which separate in the branching of the process. This fact caused fresh attention to be given to a half-forgotten observation by Max Schultze, made 40 years ago, that the axis cylinder of a nerve fibre is not a homogeneous body but consists of numerous fibrillæ, each continuously separate from the others, and that these diverge as the fibre widens to join its cell. Max Schultze's observations have been abundantly confirmed and so also has another fact he discerned—that these fibrils pass through the cell body without interruption. The fact cannot be observed of all the fibrils but it can be of some, and it is a condition that we cannot doubt if true of some must be true of all. None have been seen to end in the cell.

The fibrils thus pass through the cell body to the branching processes or dendrons, and conversely some fibrils of these can be seen to pass into the cell body towards the axon; others can be clearly seen to curve near the cell wall to another dendron. Thus, the dendrons communicate with each other through the cell and also receive the fibrils of the axon. Their finer divisions or "dendrites," as I said, seem to disappear in the matrix, but by silver staining they are revealed and seen to end in a small knob or in a point and their terminal portion bears small bud-like projections on the surface. It is this fact of their termination (discovered by Ramon y Cajal) which is relied on as evidence of the discontinuity of the neurons. It is another fact which, if demonstrably true in some instances, may reasonably be assumed to be true in all. Some investigators, indeed, have thought that a fibrillary network outside the cell may afford a means of union between conducting structures but others see in it only a special condensation of a trabecular-supporting substance believed to form the spongy framework of the matrix. Before staining agents can reveal structure hardening agents have to increase the consistence of the substance and multiply many times any original difference that exists, and in this lies room for varied misinterpretation.

To prevent mistake I may point out that our nomenclature is imperfect. The branching processes are "dendrons" and their branches "dendrites," but we have no other name for their terminal portions. The long axon, of which some cells have more than one, also ends in branches which we term "axites." If we wish to speak of all the terminal branches of a neuron—dendrites and axites—we can call them "neurites."

The significance of the fact that the fibrils of the axis cylinder pass through the cell and do not end in it is very great. On it all the practical importance of the neuron theory depends. Yet, strange to say, it has been imperfectly recognised, even by some of those who have contributed largely to the establishment of the facts, although others have seen it clearly. The continuity of the conducting fibrils precludes the old assumption that the nerve impulses arise within the cell. Where there is an unbroken course there can be only conduction. It is true that impulses can be produced in a conducting fibre by physical or electrical irritation, but they are quite unlike the ordered impulses essential to function. For these we can only look to the ends of the conducting elements, that is, to the terminations of the dendrites. The cell must be regarded only as the vital centre of all the structures related to it. Many things thus become more clear. We can understand better the different direction of the nerve impulses that pass through the cell, to it, through it, and from it, and also the fact that this has no necessary relation to the direction of the vital influence which is always *from* the cell. We are better able to understand the marvellous

rapidity of the process of nutritional renewal by which lost energy is so promptly restored. The substance in which the dendrites lie must be the reservoir of plasma whence the molecules are renewed and the process there must be far more easy than it could be within the inclosed nerve cell.

It is natural that the old idea is not easy to give up. As long as the relation of cells and fibres has been known their size naturally suggested, almost compelled, the idea that they are the sources of nerve energy. The analogy presented to a galvanic battery helped to strengthen the opinion. But the wires end at the galvanic cell and the discovery that the fibrils do not end in the nerve cell destroys the analogy, or rather transfers it to their multiple endings. Multiplicity may compensate for size and may even more than compensate. The dendrites related to each nerve cell may be 20 or 50 in number. The molecules of nerve substance may do more in the aggregate if grouped in smaller masses than they could if collected together, and, as we have seen, persistent work, which depends on nutritional renewal, must be much facilitated by subdivision.¹

If conduction throughout the nervous system is by a succession of neuronical impulses, each of which is excited by a process of stimulation of the neurite endings, we may perceive one noteworthy fact. The conception brings into harmony the origin of the nerve impulses in the centre and in the periphery. The sensory nerves, at their distal ends, divide and ramify—that is, their fibrils separate into smaller and smaller groups and finally end in structures the special character of which enables various forms of energy to excite nerve impulses in them. The impulses thus arise by a process of stimulation and their degree is influenced in part by the nature of the stimulated structure. So it seems to be in the nerve centres; there also each neuronical impulse is excited, not conducted. But the stimulating energy there seems to us to be of the same nature as that which is excited, although the latter may differ in degree.

Facts have been described which seem to constitute definite ground for ascribing to these dendrite endings some degree of contractility, a property which would be of the highest importance on account of its influence on our conceptions of disease. The dendrites end, as I have said, some in a point, others in a small knob, and they present numerous bud-like projections on the surface. The contractility which they have been thought to possess is believed to influence their size and surface, to permit the diminution or increase of the bud-like projections they bear. There is no intrinsic improbability in such capacity for physical change. They lie in a substance that is semi-diffident and would readily permit such an alteration. A minute degree of change would make a great difference in the degree of receptivity of stimuli from adjacent dendrites, as was, indeed, suggested long ago by Ramon y Cajal, the discoverer of the discontinuity. The fibrils and their endings are believed to consist of two elements, a supporting spongoplasm and a hyaloplasm. The latter is of less consistence, but on it their function depends. Quite similar elements are now believed to constitute muscular tissue and its contraction is ascribed to a movement of the hyaloplasm in the meshes of the spongoplasm. Effective differences in nature may exist between substances that we cannot distinguish, but it is certain that muscle substance comes nearer to nerve substance in nature and function than any other known material of the body. It is a striking fact that the motion of the hyaloplasm of muscle should occur from a stimulus which reaches it by the hyaloplasm of nerve. We cannot deny the possibility that the mobility which muscle possesses in so high a degree may be possessed in some measure by the central nerve endings.

Because we cannot deny we are not therefore justified in affirming. What evidence is there of dendritic mobility? We must put aside as incredible the assertion that cilia-like movements of the dendrites have been actually seen in a minute translucent crustacean (Leptodera). More important is the observation, confirmed by several workers, that the influence of chloroform and morphine is to make the dendrites shorter and especially smoother in surface. Such agents are said to cause the projecting buds almost to disappear, a change that would greatly lessen the extent of receptive surface. Another asserted fact is still more

significant. Such a change is said to reach a very high degree in hibernating animals when the condition is compared with that in the brain of the same animals in their active state. It is unfortunate that more attempts have not been made to confirm or disprove this observation. It is one of the highest importance.

We cannot separate hibernation and ordinary sleep. The difference between them is simply one of degree. The fact suggests that ordinary sleep may depend simply on dendritic retraction. We may conceive that the process endings of the higher cerebral structures are thus withdrawn from the influence of the lower structures which act on them in the waking state of continuous excitation, the nerve elements pass into comparative rest, in which nutritional renewal can take place without more disturbance than the gentle functional activity which the mere process of renewal seems to involve. When this is adequately achieved the dendrites may lose their retraction and again become receptive, or a vigorous impulse to some of the lower neurites may be sufficient to bridge over the increased space and reach the resting structures, to re-excite the active state of approximation, a state which spreads at once through the whole series. By incomplete withdrawal and partial relation to lower neurons the phenomena of talking in sleep and somnambulism become compatible with the explanation. Such, or something like it, is the dendritic theory of sleep. Of course it is hypothetical but it constitutes an attempt to explain sleep for which we may otherwise search in vain. Consider the explanation of the nature of sleep, the best that is to be found, given in Foster's "Physiology" (p. 1552). "It has been urged that during sleep the brain is anemic but this anemia must be regarded as an effect rather than a primary cause. The essence of the condition is rather to be sought in purely molecular changes; and the analogy between the systole and diastole of the heart and the waking and sleeping of the brain may be profitably pushed. We cannot at present make any definite statements regarding the nature of the molecular changes which determine this rhythmic rise and fall of cerebral irritability," &c. The difficulties of assigning a dominant part either to products of metabolism or to the supply of oxygen lead to the necessity of assuming that some influence of an inhibitory mechanism must act on the respiratory centre, a necessity "which indicates that the explanation of sleep is at present inadequate."

One distinct conclusion may be drawn from the account I have abridged: it is that the dendritic theory of sleep does not replace any clear or satisfactory explanation. If it is true, it enables us to form a definite conception not only of sleep, but of many other conditions of action and inaction in the central nervous system. The facts, for instance, of more or less facile action in certain lines has been explained by less or greater "resistance" and the more ready action produced by repetition is ascribed to a "diminution of resistance." But this is merely another way of stating the facts observed. It has the semblance of an explanation but does not explain. If we conceive, and if we are justified in conceiving, that repeated activity of a certain character leads to an increased development and closer approximation of the dendrites concerned, we have an intelligible and real explanation. Muscles increase in size with use, and if the elements of which the dendrites consist resemble, even remotely, those that constitute muscle substance, why should it not also be so with them. The substance in which the cells and their processes and the distinct fibres lie is also said to consist of a mobile hyaloplasm in a network of slightly firmer spongoplasm. These are materials of which structures so different as nerve fibrils and muscle substance are said to consist. But there must be essential differences of constitution and function which we cannot disarm. We cannot doubt that much more is to be learned of this "matrix," when we remember that the dendrite endings were invisible within it until revealed by silver staining. Through it must pass the influence which one dendrite exerts upon another, an influence which may be conducted as a form of nerve energy which excites a fresh impulse in the dendrites of the neuron it affects, just as the nerve impulse passes through the sarcolemma to the muscle substance.

However great may seem the difficulties of this dendritic theory, it is worth while, after duly considering them, to revert to the view that the nerve cells are the source of the nerve impulses, and consider the same problems and difficulties in relation to them. I think it will be felt that the difficulties

¹ The chemical nature of the processes is outside the range of this lecture, but the suggestive sketch given by Dr. Mott at the close of his address on the Pathological Investigation of the Causation of Insanity (THE LANCET, June 2nd, 1906, p. 1520) seems in harmony with the views here expressed, especially in relation to epilepsy.

are not less, but greater. The less our knowledge the less we feel the unintelligible, because it is vague and undefined.

The effect of the theory on our conceptions of disease is not less than on our thoughts of normal processes. If the nerve impulses arise in the numerous dendrites which lie around each cell and are excited through the less specialised substance in which they lie, it is to them we must look for the seat of what is called functional disease. At least we must look to them chiefly. It is conceivable that changes in the matrix, through which the excitation must pass from adjacent endings, may also play a part in deranging their excitation and thus the source of symptoms may be complex. But the nerve cells can have no part in purely functional disturbance. Yet it is to them only that attention has been directed in the innumerable attempts to discern a visible cause for the symptoms, or traces of change the disturbance may have produced. If the dendritic theory is correct, it is not surprising that all such attempts have been unsuccessful. They are so, even in the case of diseases that might be expected to be attended by conspicuous alteration. The nerve cells often suffer; their degeneration entails and accompanies decay of their fibres; it is conspicuous in degenerative diseases of the brain; but no alteration accompanies mere derangement of the nerve impulses, nor should do so, if these simply traverse the cells.

¶ Consider chorea. Its great symptom is disturbance of the motor impulses, apparently at their origin in the cerebral cortex. They become apparently spontaneous, insubordinate, irregular in time and degree, occurring when not intended, ceasing when they should be maintained. Do we not get a better conception of it if we regard it as a disorder of the dendrites instead of one of the nerve cells? If the dendrites possess some mobility a disturbance of their nutrition may derange this and we can easily picture a pathological conception of the disease. Compare with this our thoughts of the disease if the impulses proceed from the nerve cells. Much search has been made for changes in these but in vain.

Paralysis agitans is a disease that has baffled efforts to find traces of its cause or consequences in the nerve cells of the cortex. Whether search in lower regions of the brain will be more successful remains to be seen. At present we must rest on the fact that its features suggest that it is due to a peculiar senile degeneration in the motor cortex. This seat is suggested by its common unilateral course and by the occasional association of mental symptoms. But disease of the motor cells would entail degeneration of their fibres in the lateral columns but the signs of this, excessive wrist-jerk and knee-jerk, with foot clonus, are not met with in any typical case of the disease. We have had therefore to assume that it is a "peculiar form" of degeneration, which is simply pushing it back into the unknown. But the difficulty vanishes with the disappearance of the energy-producing function of the cells. The tremor consists in intermittent motor impulses in antagonistic muscles and though their arrangement may possibly be determined in the spinal cord, their origin must be sought where the impulses originate—in the dendrites of the motor cortex. We can thus understand why the cells are unaltered and their fibres undegenerated. The malady remains mysterious, but one mystery disappears if we regard it as a senile dendritic disease. A sudden shock of great alarm may cause trembling quite like that of paralysis agitans and we can conceive a sudden nutritional derangement of the dendrite endings from the shock. It is conspicuous in a frightened horse which can make no attempt to escape. On a ferry boat a horse will tremble violently because the natural effect of alarm, motion to escape, is impossible. The unrelieved excitation of the motor structures so deranges them as to cause violent tremor. In man this effect has been known to persist and endure as typical paralysis agitans. So, too, the effect of sudden alarm may actually persist as chorea. The facts harmonise with the opinion that both are cortical diseases. They do not, of course, prove that these are dendritic diseases, but the dendritic view alone makes them intelligible.

In epilepsy we have a sudden intense activity of the sources of nerve energy in the cortex of the brain, often spreading through it with instant rapidity, sometimes beginning in one spot and spreading more deliberately. On the theory we are considering we must regard its seat

as the motor dendrites. We know that the dendrons are connected by fibrills which pass through the cells, but we can conceive that a special form of excitation may pass directly through the series, with an extension almost explosive in its rapidity. If it seems to be difficult to conceive the process as occurring in the dendrites, pass back to the nerve cells and the difficulty is at least not less.

The inhibitory character of some slight attacks must be ascribed to the reversal of the effect of a slight "discharge" and is obscure whatever opinion be held as to its seat. It is a phenomenon that seems to depend on the nature of the process and a conception of it is possible if the dendrites are its seat. The purest type of functional disturbance in the nervous system is temporary inhibition. An upper canine tooth was extracted; there was immediately complete drooping of the eyelid on that side and for several hours it could not be raised. Stimulation of the fifth nerve causes closure of the eyelid to save the eye from danger. For this there are relaxation of the levator and contraction of the orbicularis. By the dendritic theory the stimulus may be conceived to have caused a contraction of the dendrites of the levator nucleus in such excess that it was long before it passed off and allowed them to receive the impulses to cause contraction in the muscle. Thus we may conceive a physical mechanism for the arrest of action which, if true, is a distinct gain to our clearness of thought.

Few can doubt the reality of what is called hysterical hemianesthesia. It is a definite fact that some patients are unable to feel pain on one side, on the limbs and body, while feeling it acutely on the other side, and that this loss may suddenly disappear. It must therefore be of what we call "functional" nature, and there, in mystery, we have to leave it. But the dendritic action enables us at least to form a conception of its nature, although not to explain it. During sleep it is assumed that all the dendrites by which the highest centres are in relation to the lower undergo a change of form by which they cease to be susceptible to any but very strong excitants. In this strange hemianesthesia, from some cause we cannot fathom, such a change may occur in the highest sensory centres and it prevents the impulses of pain reaching those that subserve consciousness. The receptivity may be suddenly restored by some influence which permits the dendrites to resume their normal state, and a special condition of the highest psychical centres may have this effect. Except by such a hypothesis, the facts are wholly unintelligible. It is not conceivable that the will can cause pain from one half of the body to be unfelt. It must be some physical mechanism such as the theory presents. If, as some believe, loss of sensation occurs in part of a limb from true functional disturbance in the spinal cord, it may have the same explanation, since wherever nerve cells—i.e., distinct neurons—intervene in a conducting path, the transmission must be by stimulation of their dendrite endings. This, too, may be the mechanism of the peculiar inability to expel the contents of the bladder which sometimes results from an operation on the rectum. To say that such phenomena are the result of "inhibition" is little more than to cloak our ignorance in words, for it is only a statement of the facts in other terms.

So with many other problems of the action of the central nervous system, both normal and abnormal. Those I have mentioned are enough for my purpose, which is to show how great is the practical importance of the asserted facts and of their significance. They enable us to form conceptions of normal and abnormal action not only clearer but distinctly in advance of those that before were possible. When once we have become accustomed to them it is not easy to go back to the ideas they displace, and we cannot but desire that the new may be proved to be true.

LARYNGOLOGICAL SOCIETY OF LONDON.—The following have been elected officers and members of council for the ensuing session, 1906-07:—President: Dr. J. B. Ball. Vice-Presidents: Dr. F. Willocks, Mr. Charters J. Symonds, Dr. G. William Hill, and Dr. P. Watson Williams. Honorary treasurer: Mr. H. B. Robinson. Honorary librarian: Dr. StClair Thomson. Honorary secretaries: Dr. H. J. Davis and Dr. W. Jobson Horne. Council: Sir Felix Semon, Mr. Philip R. W. de Santi, Dr. J. Middlemass Hunt, Mr. S. Paget, and Dr. Atwood Thorne.

A Lecture

ON

STUTTERING.

Delivered at the Medical Graduates' College and Polyclinic, London,

By W. S. COLMAN, M.D. LOND., F.R.C.P. LOND.,

PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; PHYSICIAN TO OUT-PATIENTS, ST. THOMAS'S HOSPITAL.

LADIES AND GENTLEMEN,—Although this common complaint does not cause impairment of the general health it is a most serious disability. It is not merely an annoyance to the stutterer himself and a trial to those with whom he converses but it closes to him many careers, such as the public services. In most walks of life, too, a stutterer is severely handicapped when trying to gain employment. Unfortunately, its seriousness does not impress itself until he has reached adult life, when the habit is extremely difficult to overcome. It is, therefore, important for the medical adviser to make parents realise the importance of attending to the defect while the boy is young. It is true that many, perhaps the majority, of those who stutter in childhood recover spontaneously but if the defect continues after the age of eight years it should be seriously taken in hand. Between the ages of eight and 12 years, when boys are old enough to understand what is required of them and not too old for the habit to have become ingrained, is the best time for successful treatment.

Stuttering is a very common and world-wide affection. A stutterer was often introduced as a comic character on the stage in Greek and Roman days as in our own. It is common in the East and in China it has the suggestive name of "tchi-ko"; it is also known among the negro races of Africa. In this country it appears to be especially common and occurs among all classes, being about four times as common among boys as among girls. It usually begins in early childhood. It is often said loosely that a child has stuttered "ever since he began to talk." But careful inquiry usually shows that at first he talked in the ordinary way and that the stutter did not make its appearance until the age of three or four years. It may commence much later, especially at some epoch in the child's life, such as at the second dentition or when he first goes to day school or boarding school. At such epochs, too, a slight stutter often becomes intensified and one which has been recovered from may reappear. A similar reappearance of a lost stutter may occur if the boy goes to live in a foreign country where he has to talk in an unfamiliar language.

Of the etiology of stuttering we know nothing definite. Direct inheritance is rare and possibly imitation is the chief factor when father and son are affected. There is usually a well-marked neurotic inheritance, others in the family having various forms of nervous complaints. But I have not been able to confirm Charcot's statement that stuttering and ordinary facial paralysis frequently occur in the same family. Shocks, frights, and debility after some acute illness are the causes to which the onset is most frequently attributed by parents. Imitation is undoubtedly an occasional cause, children having often been known to start the habit when put in charge of a stuttering nursemaid. A friend of mine who was extremely fond of horses and was hardly to be kept out of the stables acquired a most obstinate stutter from the groom. Adenoid vegetations are often met with and are important as a predisposing cause, since they tend to prevent the proper filling of the chest with air. When present they should be removed as a preliminary measure, although it must not be expected that their removal will lead to a prompt cessation of the stutter. At one time it was supposed that there were malformations of the mouth and tongue, but the fact that the stutter is only occasional would be sufficient to dispose of that idea. Early in the last century there was a short period of surgical enthusiasm based on this erroneous notion and extensive divisions of lingual muscles were carried out. As was to be expected, no improvement took place and in many instances the results were disastrous. The defect is

not a structural one but is due to some faulty control of the nerve centres over the muscles which bring into play the mechanical arrangements for the production of articulate speech. We must therefore spend a little time in briefly reviewing our knowledge of the production of speech. Those of you who want fuller information should read Wyllie's splendid work on the Disorders of Speech,¹ which deals not only with stuttering but with the development of speech in the child and in the race and also with aphasia. The matter of this lecture is based on Wyllie's teaching.

In the production of speech we have three mechanisms under control of the central nervous system, each with a complex arrangement of muscles:—(1) the expiratory muscles to supply a blast of air; (2) the laryngeal muscles to approximate the vocal cords and keep them at a suitable tension for the production of voice; and (3) the muscles of the lips, tongue, and soft palate to alter the shape of the mouth and vary the size and shape of the orifices by which the vibrating air issues so as to modify it into the various consonants and vowels. In normal speech these three mechanisms work smoothly, each coming into play at precisely the proper time. In stuttering this perfect coördination by the nerve centres every now and then breaks down. Most frequently it is the larynx supplying the vocal element which lags behind, while violent but disorderly movements take place in connexion with the articulatory mechanism. Wyllie uses the playing of a violin as a useful illustration of exact timing of two mechanisms. The bow hand (corresponding to the laryngeal mechanism) must move in perfect coördination of time with the string hand (corresponding to the articulatory mechanism). If there is the least disturbance of this coördination discord results. Beginners, like stutters, often concentrate their attention on the string hand and may even forget to use the bow in their efforts, just as stutters make violent articulatory efforts but forget to vocalise. It is not only necessary that these three mechanisms should work perfectly together but we must see that each of the three perfectly carries out its own function. The chest requires to expand well and to be kept well filled, the larynx requires to be adjusted so as to produce a full tone of voice, and the muscles of the mouth, &c., must be skilfully used so as to give the proper pronunciation of the consonants and vowels. Vowels are produced by altering the size and shape of the buccal cavity by raising, depressing, or varying the shape of the tongue. In this way different over-tones are produced which modify the voice into vowels. Consonants are produced by movements of the lips, the tongue, and the palate. The site at which they are produced can be grasped by getting familiar with Wyllie's physiological alphabet which shows all the consonant sounds in use in the English language.

WYLLIE'S PHYSIOLOGICAL ALPHABET.

I.—VOWELS.

y—ieaou—w.

These should be pronounced in the Latin manner as *ē, ē, ē, ē, ē, ē*. *y* and *w* are consonants, not vowels, but have very close relationships to the vowels, initial *y* being very closely related to *i* and initial *w* to *u*.

II.—CONSONANTS.

	Voiceless oral consonants.	Voiced oral consonants.	Voiced nasal resonants.
—			
Labials.	P	B	M
(1st stop position).	(W)	W	
Labio-Dentals.	F	V	
Linguo-Dentals.	Th¹	Th²	
Anterior	S	Z	
Linguo-Palatals.	Sh	Zh	
	T	D	N
(2nd Stop Position.)	(L)	L	
Posterior	K	R	
Linguo-Palatals.	H or Ch	G	Ng
(3rd Stop Position.)		Y	
		(R)	ç

The voiceless *W* and the voiceless *L* have been given above within brackets, the former being now almost confined to Scotland, and the latter being peculiar to Wales. The burring or uvular *R* is also given within brackets.

¹ Edinburgh, Oliver and Boyd.

[The exact position taken up by the lips and tongue in the case of each consonant was then demonstrated. Full descriptions will be found in Wyllie's "Disorders of Speech," Gutzmann's "Störungen der Sprache," and in Schäfer's "Text-book of Physiology."]

It is very important in connexion with our subject to remember that the majority of the consonants have a vocal element and are hence called "voiced" in Wyllie's alphabet. Beside these factors in the production of vocal speech there is another, the shape of the chest. The actual sound produced by the larynx (as can be easily demonstrated on a cat's larynx after removal from the body) is a very small "thin" sound. It is amplified and intensified during life owing to the chest acting as a resonating chamber. Hence the importance, when employing a good "carrying" voice (as when speaking in a large hall), of keeping the chest well filled and never falling back on the reserve air in the chest.

When we come to examine a stutterer we usually find that (quite apart from the stutter) he has a faulty method of producing his voice. This is best demonstrated by making him bare his chest and read aloud from some book. We nearly always find that he is a shallow breather. Respirations are mostly abdominal, the upper part of the chest scarcely moving at all. Secondly, he manages his breathing badly, allowing the air to run out until he has to take a catching inspiration (often in the middle of a sentence) instead of taking a full inspiration at the stops. Thirdly, his voice is nearly always low-pitched, monotonous and muttering, and usually hurried. Articulation is often slovenly with a tendency to clip short syllables and to slur the internal consonants of a word. As we shall see, the most important point in treatment is the removal of these defects.

Coming now to the investigation of the actual stutter you will notice that as the patient is reading there is a sudden interruption of speech at the commencement of certain words. He usually drops his voice just before the difficulty occurs and then comes to a dead stop, making evident and often violent efforts to get the word out. Suddenly he succeeds and the word is ejected in an almost explosive fashion and the succeeding words tumble out rapidly until utterance is checked by a fresh stutter. It is noticed that (except in rare instances) he only stutters on the initial consonant of a word. (For instance, a man who stuttered when saying "butter" would have no difficulty at all when the "b" occurred within the word, as in "club" or even in "tubular," where the "b" begins a syllable.) It is only in exceptional cases that there is any stuttering on initial vowels. As the patient goes on reading you will notice that the initial consonant which gives rise to trouble at one moment may be pronounced a little later with perfect ease. He may again stutter several times in a single line and then get through a whole paragraph without any hesitation. Each stutterer has his own individual defects but, speaking generally, the explosives P, B, T, D, K, G (hard) give rise to trouble most frequently, though M and N are also common stumbling-blocks. Careful note should be made of the words on which he stutters and they should afterwards be carefully scrutinised to see if they present any common feature, such as the inclusion of some consonant which the patient pronounces with a lisp. The knowledge that this letter is approaching within a word may cause panic, so that he stutters on the initial consonant of the word which contains it. A boy, for example, who cannot pronounce "l" properly may stutter at the commencement of any word which contains it, such as pillow, fluff, girl, translate, &c., and the lisp must be conquered before he has any chance of getting rid of the stutter. I may mention two illustrative cases. One was that of a young man who had a very bad stutter. When I saw him he had just entered on a professional appointment in which it was necessary for him to read out the contents of documents. This he found impossible because of his stutter. He was very sensitive about it and was contemplating resigning his post. On testing him I found that each of the words at which he stuttered contained an "r," a consonant which he pronounced like "w," calling a barrow "bawwow," so that when approaching a word with an "r" in it he would get into a panic (without being conscious of the cause) and stutter on the initial consonant. The second case was that of a clergyman who had a groundless anxiety lest he should omit an "h" when it occurred within a word. He could say "Holy, holy, holy," with perfect ease but he could not say "behold" without stuttering painfully on the initial "b."

We may now consider in more detail what takes place when stuttering occurs. Three divisions of cases of stuttering may be conveniently made: (1) Simple stuttering; (2) stuttering with associated noises; and (3) stuttering with associated movements.

1. The first form is the most common. When the stutterer comes to a difficult word he makes obvious attempts to articulate the consonant. He throws all his energies into the muscles of his lips and tongue to put them in their proper place but his vocal cords not being properly adjusted no sound is produced, and as his glottis remains closed his face often becomes congested from his fruitless efforts. His laryngeal mechanism, in fact, has not come into play at the proper time. This form is seen in ordinary people under conditions of violent emotion, especially anger, as when a furious man is unable to articulate the initial letter of the expletive he wishes to hurl at the person with whom he is annoyed.

2. Not uncommonly in addition to the hesitation or stutter there are "associated sounds." These most frequently take the form of a rapid repetition of the consonant sound before the word is suddenly ejected—e.g., g-g-g-g-ood, m-m-m-m-orning—the form almost invariably selected for imitation on the stage. Sometimes inarticulate whimpering noises are made during the period of hesitation and more rarely some catch word is interpolated. Usually this word is quite meaningless, "hedera," "nana," &c., though occasionally a real word may be introduced quite inappropriately. These associated sounds may also occur in non-stutterers. We are all familiar with the recurring "er" of a nervous speaker. Some nervous speakers also frequently interpolate a catch phrase whenever they hesitate for a word, using such words as "as it were," "in a sense," "for instance," often quite inappropriately.

3. There may be "associated movements." These show great variety. There may be simply slight grimacing or there may be most disfiguring facial contortions. Some stutters raise their arms or fidget with their feet. In the most severe case I have seen the stutterer become red in the face, his mouth was drawn strongly to the left, his arm was drawn up, and the whole body half rotated exactly as if an epileptic paroxysm were developing. Suddenly the spasm would pass off and the body jerk back to its normal position, the word being ejected at the same instant.

"Tricks" used by stutters.—It is well known that stutters have no impediment whatever when they sing. Consequently when in difficulties they may evade the stutter by singing or intoning the word. If this is done often, however, a sing-song delivery may be acquired which is likely to persist long after the stutter has been overcome. Another "trick" is to draw in breath when any difficulty occurs. This is never to be recommended. The patient ought to be instructed to do the very reverse—to expire and to vocalise strongly. For if he draws in air he is very liable to vocalise with inspiration, the "draw-back phonation" of Wyllie. This "draw-back phonation" may be simply a little chirp or the stutterer may vocalise the first syllable on the inspiratory current of air, producing a very disagreeable effect.

With regard to treatment everything should be done to get the boy into as good general condition as possible by tonics and suitable regimen. No drug treatment has any effect on the stuttering itself. Put very shortly, the main objects of treatment are: 1. The removal of the shallow, ill-managed respiration which we have seen is so frequently present in stutters. If the shallow breathing is due to obstruction this should be removed. Systematic breathing exercises should be taught and practised daily. 2. He must be taught to speak from a well-filled chest. 3. He must be taught to speak with a resonant and modulated voice instead of the low muttering intonation the stutterer usually adopts. It is necessary to demonstrate the difference between a full resonant voice and shouting and he must be made to practise the former. 4. He must learn to speak slowly and distinctly, making all the consonants clear. It must be impressed on the patient and his friends that this practice must be kept up until the improved mode of breathing and of using his voice has become habitual to him and that this can only be arrived at after some months of diligent hard work. If this is done special treatment for the stutter often proves unnecessary. Whenever the means of the patient permit the instruction should be carried out by the medical man himself or by some experienced teacher under his direction on these lines. Or the boy may be sent away from home to be under the care of

some specially skilled teacher. There are several admirable teachers, but careful inquiry should always be made, as some who profess to undertake this kind of work are not altogether trustworthy. Often, however, the limited means of the parents preclude the adoption of skilled teaching and we have to fall back on the services of the mother or some other relative. But it is difficult to get the boy to apply himself as diligently if a relative is instructing him. Assuming that we have a suitable relative, say the boy's mother, the first step is to instruct her, on the lines sketched out in this lecture, in the proper production of voice and speech and in the faulty methods employed by the stutterer, and she must acquire an intelligent grasp of the principles aimed at in treatment before commencing. She must be shown how to give the boy suitable breathing exercises and to give him daily practice in reading aloud in two lessons at least half an hour long. In order to insure that his chest is well filled and that he speaks with the full "carrying" voice which he has to acquire it is a good plan to make him read from some interesting prose book in the open air or in a large long room, such as a warehouse or barn when either of these is available. In towns this is rarely practicable and then the best expedient is to place the boy in an adjoining room with the door ajar or open, so that he has to raise his voice and speak very distinctly in order that every word may be distinctly heard in the next room *without shouting*. He must be corrected each time when he is letting his voice drop (i.e., speaking from an empty chest) and reminded to fill his chest at each stop. He should not be worried about his stutter at all at first. His mother should have a copy of the book from which he is reading and should underline each word on which he stutters. He should be made to practise these words by himself and run over them before the next lesson. If there is any local facility for his getting elocution lessons advantage should be taken of it. Another useful exercise for training him to keep his chest well filled is to practise singing sustained notes. He must be encouraged to take all these exercises seriously and to work at them with all his energy and with untiring perseverance. From three to six months will be required in any severe case and for the first month little apparent progress will be made. Hence discouragement and carelessness in both patient and teacher are apt to result and the medical man ought to witness the lessons from time to time to encourage the patient and to suggest improved methods to the mother when necessary. This home method which has been outlined is much inferior to skilled tuition and takes longer, but where the latter is not feasible and the patient and teacher will throw themselves earnestly into the work very good results are in time obtained.

After these exercises have gone on for some time improvement in the stutter is nearly always seen and it may disappear. If it does not go when the respiration and vocalisation have been corrected special attention must be paid to overcoming the difficulty. The patient must be made to grasp the idea that it is the laryngeal action which is behind-hand and that he must make increased effort to produce voice. If the consonant which gives difficulty is a "voiceless" one, as P (see physiological alphabet *supra*), he must try to get out the succeeding vowel and he will find it quite easy to add the consonant. If the consonant be a "voiced" one, as B, he must be shown that it contains a definite vocal element and he must learn to throw his energy into getting this out instead of the labial element. If there are any associated gestures he should do his reading practice in front of a mirror. Finally, it has to be impressed on the boy and his relatives that the improved method of using his voice must become habitual by long practice and that this practice must not be limited to his times of instruction but that he must carry it on in ordinary conversation. Given time, great perseverance, and an average amount of intelligence the majority of stutters under 14 years of age may look forward with confidence to conquering their distressful disability.

MUNIFICENT BEQUEST FOR THE PREVENTION OF CONSUMPTION.—Mr. Georges Montefiore-Levi of Brussels, formerly a member of the Belgian Senate and president of the Association of Engineers, who founded and endowed among other institutions the Liège Electrical Institute and the Liège Government sanatorium, has left specific bequests to Jewish and general charities on the continent to the value of over £35,000. A portion of his residuary estate, probably exceeding £100,000 in value, is to be applied for the prevention of consumption.

MICROBIC CYANOSIS.

BY G. A. GIBSON, M.D., D.Sc. EDIN., LL.D. ST. AND.,
PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH;

AND

CARSTAIRS C. DOUGLAS, M.D., D.Sc. EDIN.,
PROFESSOR OF MEDICAL JURISPRUDENCE AND HYGIENE AT ANDERSON'S
COLLEGE, GLASGOW.

THE conception of blood destruction produced by toxic processes having their origin within the intestines has been steadily growing within recent years. Such an idea forms the basis, as is well known, of certain theories widely held in regard to the causation of anæmia, both primary and secondary. Into the subject of anæmia we do not intend at present to enter but some questions connected with blood changes caused by microbic activity have forced themselves upon our attention during observations upon a most interesting case and we desire to make the results of our inquiries known. It will undoubtedly be easier to render the subject clear if we in the first place briefly summarise the clinical features of the case and afterwards describe the facts elicited by chemical and bacteriological investigation. The information thus obtained will allow us to compare the different symptoms presented by the patient with those described by recent observers in the Netherlands, to whom we owe all we know on the subject, and we shall then be in a position to state our conclusions definitely.

A married lady, aged 36 years, had suffered for some years from weakness and headaches and these symptoms were frequently associated with attacks of giddiness and faintness. But the most obvious symptom was a considerable change in the complexion. The patient had blue eyes and golden hair, formerly associated with a ruddy complexion, but during the last two or three years the tint of the skin had assumed a distinctly cyanotic appearance. The face and hands were of a lavender hue, while the lips, ears, and nails were almost as dark as bilberries. For some time there had been a considerable tendency to diarrhoea and this was frequently accompanied by general gastric as well as enteric disturbance. Dr. W. F. Somerville, under whose care the patient had been for some years, requested Dr. Douglas in May, 1905, to make a general examination of the blood and urine. The hæmoglobin then amounted to 70 per cent., the erythrocytes numbered 3,360,000, the colour index, therefore, was practically 1; the leucocytes were 10,296 in number and stained films showed poikilocytosis in a slight degree with one possible normoblast. The blood was otherwise normal and thus presented the features of a secondary anæmia. The amount of the urine was 1750 cubic centimetres (61 ounces) in 24 hours. It was pale, acid, and of low specific gravity (1008), and contained faint traces of albumin and pus, but no other abnormal constituents. The amount of creatinin was diminished and the urea only reached 1 per cent., or 17.5 grammes (269.5 grains) per day. The microscope showed a few pus-corpuscles, some uric acid crystals, and one or two hyaline casts. In September, 1905, Dr. Somerville requested Dr. Gibson to see his patient along with him and the general facts which have been stated were confirmed. At that time the complexion was as has already been described. It was observed that there was no clubbing of the fingers; the vessels were healthy; the arterial pressure was moderate; while the rate and rhythm of the pulse were within normal limits. The heart was not enlarged and the only abnormality was faintness of the sounds with a slight systolic murmur near the pulmonary area. There was no change in the condition of the lungs; the liver and spleen were of ordinary size; and with the exception of headache and depression the nervous system showed no implication. The condition of the blood and the urine was as when the patient was seen in May by Dr. Douglas. On careful investigation of all the symptoms Dr. Gibson suggested that it was possible the patient might be suffering from blood destruction as the result of using aniline derivatives, which she had undoubtedly employed with great freedom for the headache that had for long been such a prominent and persistent symptom. The presence of methæmoglobin in the blood as the result of poisoning with aniline substances has been recognised since Rayner¹ first described it. It has also been

¹ Brit. Med. Jour., 1886, vol. i., p. 294.

thoroughly investigated by Müller² and Brown.³ It was arranged between Dr. Somerville and Dr. Gibson that the patient should, if possible, abstain from the use of the synthetic drugs for some time and that a consultation should be held at a later period with the view of discovering whether any improvement had taken place. During the winter and spring the patient remained in Glasgow under the care of Dr. Somerville; she only took comparatively small doses of phenacetin and used every means which seemed likely to improve the general condition. In May of the present year she was again seen by Dr. Gibson and the blood was again carefully examined. It showed 48 per cent. of hæmoglobin and 3,200,000 erythrocytes, the colour index being therefore 0.75. The number of white corpuscles was on this occasion 7400. Stained films showed a greater degree of poikilocytosis than formerly, but the cells stained well and no nucleated red corpuscles could be detected. There was no departure from the normal relation on making a differential count of the whites, the polynuclear neutrophiles numbering 65, the small lymphocytes 23, and the large 5, while the eosinophiles were 2 per cent. The peculiar grey tint of the face and hands was as deep as formerly, while the blackish-blue colour of the lips, ears, and nails was quite as intense as it had been. It occurred to Dr. Gibson that the cyanosis was probably due to the presence of methæmoglobin and he suspected that this might be due to intestinal changes. This condition has been described by Stokvis,⁴ Talma,⁵ and Hijmans van den Bergh.⁶ The investigations of these three observers have lately brought before us a condition which had not been previously described as the result of changes in the hæmoglobin through toxins having their origin in the intestines, whence they are absorbed into the blood. The original case described by Stokvis was characterised by foetid diarrhoea. The patient had drumstick fingers but no œdema. No change could be determined in the heart, lungs, liver, or spleen, and only towards the end of life was there some albuminuria with tube-casts. Stokvis believed the cause of the cyanotic appearance to lie in the presence of methæmoglobin but no attempt was made to find out the mode of production of the blood changes. After death it was found that the patient had suffered from ulcerative enteritis and subsequent subacute parenchymatous nephritis. Talma described three cases of what he termed intra-corpuscular methæmoglobinæmia. In all of these cases the circulatory organs were practically normal, but the blood contained methæmoglobin, described as present in the corpuscles and not free in the plasma. No hæmoglobinuria was present in any of the three cases, but all showed the presence of much iron in the renal secretion. In all of them the condition of the intestinal tract was obviously the origin of the principal symptom. Hijmans van den Bergh has described four cases of sulphæmoglobinæmia with profound cyanotic appearances taking their origin in serious intestinal changes. He has further narrated the cases of three patients suffering from enterogenous methæmoglobinæmia, and in this connexion has taken advantage of the observations of Steensma⁷ upon the presence of nitrites. He found in these the connecting link between the intestinal troubles and the resulting blood changes. The investigations of Hijmans van den Bergh, assisted by Mejuvrow Grutterink, were of the most exhaustive character and merit careful study.

In consequence of his suspicions regarding the nature of the case Dr. Gibson recommended that Dr. Somerville should again call in the assistance of Dr. Douglas with a view to the spectroscopic examination of the blood and the bacteriological examination both of the blood and of the secretions. This was accordingly done. Blood taken from the ear was examined both with the direct vision spectro-scope and the large table instrument. It gave the characteristic spectrum of methæmoglobin in dilute solution—the narrow band in the red between the C and D lines as well as the ordinary bands of oxyhæmoglobin at D and E. The spectrum agreed with that of artificially prepared methæmoglobin obtained by treating normal blood with aqueous solution of ferrocyanide of potassium, but the red line was much fainter in the genuine specimen. It may be mentioned that at the time of examination the patient was less cyanosed

in appearance than she often was. On the following day the urine was carefully examined. It contained nothing abnormal except a slight increase of the normal urobilin as determined by Schliesinger's test (treating the urine with an equal volume of 10 per cent. solution of zinc acetate in absolute alcohol and filtering, with development of green fluorescence).

Being very anxious to make some further observations Dr. Somerville and Dr. Douglas induced the patient (who was very nervous about these manipulations) to let the latter draw some more blood. She was not so well on this occasion and the face showed a very characteristic grey tint, while the lips were a dark grey-blue. Dr. Douglas endeavoured in the first place to get a direct spectroscopic picture of the blood while still in the vessels, as the Rotterdam observers had done, but was unsuccessful, due chiefly to want of assistance and the absence of a good lamp. When the ear was incised it was noted that the blood was extremely dark in hue. Several specimens were received into test-tubes and on the addition of water yielded a crimson solution—not a red solution as normal blood does. In concentrated solution a very marked spectrum of methæmoglobin was obtained, the red band being beautifully distinct, while the whole of the right-hand end of the spectrum was absorbed up to the orange line. In more dilute solution the red line was fainter though quite distinct and the two ordinary bands of oxyhæmoglobin appeared. On the addition of ammonium sulphide the characteristic phenomena of the methæmoglobin spectrum were perceived—that is, the red band disappeared promptly, leaving the bands of oxyhæmoglobin at D and E, while these merged more slowly into the broad ill-defined band of reduced hæmoglobin.

To ascertain the presence or absence of nitrites in the blood of the patient 100 cubic millimetres were diluted with 20 times their volume (two cubic centimetres) of nitrite-free water. In this, as in all other instances, the test employed for nitrites was the extremely delicate one which consists in adding one cubic centimetre each of a solution of sulphanic acid and of naphthylamine in acetic acid to the liquid to be tested, when, after the lapse of a longer or shorter time, the most minute trace of nitrous acid is indicated by the development of a fine pink colour. As little as $\frac{1}{10}$ milligramme ($\frac{1}{1000}$ grain) of nitrous acid can be thus detected, the test being much more sensitive than the iodide one. The blood, thus diluted 20-fold, measured a trifle over two cubic centimetres and to it were added five cubic centimetres of absolute alcohol (nitrite free) dropped in slowly from a pipette while the mixture was constantly stirred. A dull brown colour developed and the tube was closed and allowed to stand 12 hours. The proteids of the serum had now sunk as a light-brown precipitate carrying down the pigments and leaving an almost colourless opalescent supernatant layer. The latter was pipetted off and thoroughly centrifuged, when a still clearer layer of fluid was obtained. This was again removed by pipette and treated with the sulphanic acid and naphthylamine reagent when a delicate pink developed, indicating the existence of nitrites. This was repeated with a second positive result. At the same time that the blood was taken some of the patient's saliva was obtained. This also gave a distinct reaction for nitrites. Presumably normal saliva, tested at the same time, gave a slight reaction but that in the case of the patient was much more marked, a fine rosy-pink tint developing. The saliva also responded to the zinc-iodide-starch test for nitrites.

Dr. Douglas considered it important to examine the fæces in this case as there had been a long history of intractable looseness of the bowels. Accordingly an ample supply was sent to the laboratory and was found to be semi-liquid in consistency, a dirty greenish-brown in colour, and extremely offensive, though by no means rich in sulphuretted hydrogen. The reaction was clearly acid. An extract made with normal saline solution showed a very slight nitrite reaction and this extract examined by the spectroscope revealed no trace of methæmoglobin. Fresh ox blood was mixed with saline extract of the fæces and kept both at room temperature and in the incubator at 37°C. to see whether any methæmoglobin could be produced. The results were negative on every occasion. The fæces were then extracted with ether containing strong acetic acid to remove any blood pigments in the form of hæmatin (Weber's test), but no evidence of blood could be obtained. Microscopically the fæces showed a very large number of bacteria and much fine debris but no blood!

⁷ Nederlandsch Tijdschrift voor Geneeskunde, 1904, II. Deel, S. 425.

The facts arrived at so far indicated that methæmoglobin was very distinctly present in the blood but absent from the motions, that nitrites were present in the blood and saliva but existed only in traces in the fæces, and that the latter possessed no power of converting normal ox blood into methæmoglobin. This seemed to point to a hæmatogenous formation of the nitrites and this raised the question as to whether the source of the latter might not be bacterial activity within the blood itself. Accordingly two loopfuls of diluted blood were inoculated into ordinary nutrient agar, plated, and incubated at 37° C. for 24 hours. At the end of this time the plate showed a number of discrete bluish-white colonies, each from one to two millimetres in diameter. Inoculations of these into various culture media yielded the following results: (1) agar slope: a thick, whitish-grey, moist streak; (2) broth: a general turbidity, settling down to a whitish deposit; (3) potato: a slight brown growth; (4) glucose-agar: gas and acid production; (5) lactose-agar: gas production; (6) neutral red-agar: development of fluorescence; (7) gelatine-stab: the tube medium unfortunately liquefied entirely owing to the very warm weather; (8) milk: marked curdling; and (9) indol reaction: attention here was directed to the point as to whether the organism had produced nitrites as well as indol in peptone water, as the cholera vibrio does. The addition of sulphuric acid alone, however, gave rise to no formation of indol red but the subsequent addition of a trace of nitrite of sodium permitted of the formation of a red tint.

Microscopically the organism was a short, stout rod, staining with the ordinary basic dyes; it was Gram-negative. Motility in hanging drop preparations was marked.

From these investigations it is clear that this organism was either the bacillus coli communis or some very closely allied organism of the colon group which was obtained in pure culture from the blood. It was apparently without the power of producing nitrites *in vitro* in peptone water but it is impossible to say what the result of its chemical activity within the blood might be. It seems to us very desirable that these observations should not be taken as final and if opportunity presents itself they will be repeated, especially those of a bacteriological nature. But a provisional reading of the case seems to be this: that the original source of mischief lies in the bowel, that a systemic infection has taken place, that nitrites are being constantly produced in the body in varying amounts (thus possibly explaining the varying degrees of cyanosis), and finally, that nitrites acting on the hæmoglobin constantly keep a varying amount of it in a state of methæmoglobin—a condition in which oxygen is very firmly united to the hæmoglobin molecule and will not separate from it for the needs of the body cells. We need hardly add that the condition belongs to the group of affections often termed false cyanosis.

We are as yet unable to venture on any positive statements as regards the therapeutic aspect of this affection. Dr. Somerville has arranged for a course of intestinal antiseptics, combined with the employment of abundant diluents, at one of the home spas for his patient, and we may probably be in a position before long to recur to the subject with information on this point. But it has seemed advisable to us to make our observations and investigations public in order to arouse interest in a condition which is so far but little known.

THE TREATMENT OF SURGICAL TUBERCULOSIS.¹

By V. WARREN LOW, M.D., B.S. LOND., F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS AT ST. MARY'S HOSPITAL, PADDINGTON, W.,
AND AT THE GREAT NORTHERN CENTRAL HOSPITAL,
HOLLOWAY-ROAD, LONDON, N.

THAT surgery is a progressive art we have amply demonstrated to us by the frequent publication of papers setting forth either some entirely new method of treatment or some improvement in technique in the performance of an old-established operation. It is perhaps only natural that the rate of progress should be often measured by the degree of novelty of the method introduced and I do not think there

are many of us who, if suddenly asked to give instances of recent surgical progress, would not immediately quote the advances that have been made of late years in the surgery of the stomach and of the prostate gland. Such brilliant examples as these are liable, however, to overshadow the steady but less obtrusive improvement that has taken place in the treatment of many other surgical conditions and I do not think I could choose a better example of this than the treatment of surgical tuberculosis. By the term "surgical tuberculosis" I mean the involvement by tubercle of such organs as the bones, the joints, the lymphatic glands, the skin, the genito-urinary system, the peritoneum, and certain abdominal and pelvic viscera, the treatment of all of which usually falls within the province of the surgeon. During the last few years there has taken place in the treatment of these conditions a steady but marked improvement, of the full extent of which we are often only made conscious by such interchange of views as I trust will take place in the discussion following this paper. A progress so gradual, as this has been, only slowly finds its way in its entirety into the current text-books of surgery, and one often finds in the same text-book strange contradictions in the application of certain principles of treatment to the same disease in different organs, accordingly as the writer's experience has drawn his attention to one or other part of the body. This must be my apology for bringing before you this afternoon such an apparently commonplace subject.

The operative treatment of cases of surgical tuberculosis during the last 15 or 20 years can be roughly divided into three periods. The first was dominated by the belief in the efficacy of incision and drainage combined with general improvement in hygiene. This was followed by an attempt to remove, or partially to remove, usually by scraping, the original focus of disease, and this naturally led to the second period, when tubercle was regarded by many surgeons as almost a malignant disease, and, where practical, the entire removal of the diseased area was insisted upon, however extensive and deforming the necessary operation might be. During this period general constitutional measures were also advocated, but, with the surgeon's attention so concentrated on the extermination of the local disease, the constitutional measures often resolved themselves into a mere pious expression of opinion, with little attention to practical detail. The reason for this is not far to seek when we reflect that the only circumstances in which extensive operations can be performed are not as a rule associated with those surroundings which we consider essential to the constitutional treatment of tuberculosis. To this particular point I wish to refer later. From the mass of experience gained during these two periods, assisted by certain recent brilliant clinical and pathological advances, there have emerged certain principles of treatment which, I believe, place us nearer to a position to control the advances of this disease than we have ever hitherto been and enable us to foretell with some tolerable accuracy the lines along which future developments of treatment will tend. I can best illustrate my meaning by giving a few examples and these are most conveniently taken from cases of bone, joint, and gland tuberculosis.

In the first period mentioned above the usual treatment for psoas or iliac abscess arising from tuberculous disease of the bodies of the lumbar vertebrae was incision and drainage. Possibly at the time of the operation every precaution against sepsis was taken, but in the subsequent daily dressings, often extending over many months, these precautions were inevitably slackened, with the almost certain result of secondary infection of the abscess cavity. The symptoms of the resulting septicæmia, whether chronic or acute, were usually ascribed to an increase in activity of the tuberculous process and further efforts were made to remove the original focus of the disease, and also to scrape away the granulation tissue lining the interior of the abscess wall, to which almost malignant properties were ascribed. Similarly, in a case of joint disease the joint was opened, any obvious tuberculous sequestra were removed, the surface was scraped, and a drainage-tube was inserted. Glands in the neck also were incised, scraped, and drained, and any recurrence was ascribed to the malignant variety of the tubercle with which the patient was infected. That the gross results were not worse than they were was largely due to the fact that, owing to the simplicity of the operative measures required, many of the cases were undertaken in the country, in cottage

¹ A paper read before the Midlands Branch of the British Medical Association at Derby on March 30th, 1906.

hospitals, or in circumstances where the after-treatment of the case could be practically conducted on lines similar to our modern open-air treatment of pulmonary tuberculosis. In such cases, even in spite of a certain amount of sepsis, the results were on the whole fairly good; but that in the hospitals of our big cities the results were deplorable I am sure all those who were students in the "eighties" and early "nineties" will agree. Such cases when I was a student often occupied beds in the hospitals for periods of six months, or even longer, requiring dressing once or twice a day, owing to the quantity of discharge. The condition of such patients was, indeed, miserable and they were a serious source of danger to other patients in a surgical ward. Almost invariably the end came from hectic fever, exhaustion, lardaceous disease, or generalised tubercle; all expressions, as I hope to show later, of the same process—namely, sepsis, whether acute or chronic.

Results such as these led surgeons to endeavour to eradicate the disease by earlier and more extensive operations. Consequently, joints and glands were excised as widely of the disease as possible and without much regard to the consequent deformity. Foci of tubercle only partially accessible, as in spinal caries, were attacked with various chemicals, such as carbolic acid, chloride of zinc, sulphur, or iodoform, and the surgeon's prime object was eradication of the local seat of the disease. Elaborate precautions were taken against sepsis, but owing to the extent of the operation or to the irritating nature of the chemicals employed, drainage was necessary in the majority of cases and drainage is always a weak spot in our armour of asepsis. Certainly the results were better during this period in respect of a sepsis but assuredly many unnecessary excisions were performed, both of glands and joints. I need scarcely labour the importance of the latter class of operations at least. Owing to the fact that such extensive operations were required, more of these cases were brought to the hospitals of our large cities and in consequence there were fewer facilities given during the immediate after-treatment for fresh air and sunshine. Efforts were certainly made to provide these essentials at convalescent homes, but because they were convalescent homes patients could not be taken into them in any numbers so long as skilled surgical attention and nursing were required. Consequently, these patients had to spend a considerable time in the wards of a large hospital while they recovered from some serious operative procedure, lying side by side to be nursed with patients on whom extensive operations had been performed for the removal of cancerous organs or for the relief of some acute abdominal disease. Although the importance of the constitutional treatment was realised in theory in practice it was neglected owing to the concentration of the surgeon's attention on the local condition.

There is nothing that is dramatically novel in the modern treatment of surgical tuberculosis. It merely consists in the practical application of certain principles, of the importance of which we have long been vaguely conscious, but which have been lately brought into prominence by the crusade against pulmonary tuberculosis and have been put on a scientific basis by the work of my colleague at St. Mary's Hospital, Sir A. E. Wright. Stated broadly, these principles are that the prognosis of any case of local tuberculous invasion depends not so much on the virulence of the particular organism introduced as upon the power of the individual attacked to manufacture certain protective substances and, further, upon the facilities for bringing these protective substances into the area involved.

Of late years Professor Metchnikoff's theory of the destruction of invading micro-organisms by the process of phagocytosis had been gradually giving way to the theory that it was to the fluids of the body that we had to look for bactericidal properties which were ascribed to certain substances termed bacteriolytins, &c. The theory of phagocytosis has, however, lately received considerable support owing to the discovery by Wright and Douglas of certain substances, in normal blood serum, which are capable of rendering bacteria susceptible of being absorbed by leucocytes. To these substances Wright and Douglas have given the name of opsonins. I need not detail the experiments by which these observers have arrived at these results, as their work is now well established and has been corroborated by other eminent pathologists. We have merely here to do with the practical application of the principles which they have laid down.

In addition to the discovery of the presence of these opsonins Wright and Douglas have also devised a technique

by which the opsonic value of an individual serum can be measured. This value they have termed "the opsonic index," and it is the result obtained by dividing the number of bacteria taken up per leucocyte, in the presence of the given serum, by the number taken up per leucocyte, in the presence of the serum of a normal individual, or, better still, of a number of individuals. The importance of this opsonic index in dealing with cases of chronic tuberculosis it is difficult to over-estimate. It gives us an accurate measure of the patient's capabilities of resistance to the disease and also enables us to measure the efficacy and progress of certain methods of treatment. For instance, it is shown that the opsonic value of the serum is increased specifically by the injection of minute doses of dead bacteria—e.g., $\frac{1}{1000}$ of a milligramme of Koch's new tuberculin. The rise in the opsonic content of the blood, so obtained, is, however, preceded by a marked fall, and to this fall Wright has given the name of "the negative phase." Should the dosage of the tuberculin be excessive or the inoculations be repeated at improper intervals of time, a persistent negative phase may be obtained and the patient's condition may be rendered less favourable. This fact has, no doubt, accounted for many of the disappointing results that have hitherto followed the use of tuberculin and which have led many surgeons to abandon its use. In a similar way the patient may be auto-inoculated from his own lesion.

In surgical tuberculosis the infection may be either sub-acute or chronic; the infected area may be easily accessible to the circulating fluids or may be so circumscribed as to be practically outside the body. On these points depends the amount of auto-inoculation that occurs. This may be excessive, leading to a persistent negative phase, or it may be too little, leading to an insufficient manufacture of protective substances, and to the consequent persistence of the lesion. These points can only be ascertained by taking a series of observations of the opsonic index and by the construction of a definite opsonic curve. The information so obtained is of the highest value in determining the treatment to be adopted. For instance, where auto-inoculation is in excess the inoculation of tuberculin would be contra-indicated, absolute rest would be employed to keep the circulation quiet in the infected area, and the surgeon would have to determine whether the local conditions were sufficiently urgent to warrant his operating during the negative phase or whether he could wait while the resistance of the individual was increased by other measures. On the other hand, when the auto-inoculation was small in amount the protective substances could be raised by artificial inoculation and measures could be taken to bring more blood to the diseased part; while the surgeon would operate with a knowledge that any escape into the circulation of toxic material from the infected area during his manipulations would not tend to depress still further the resistance of the individual but would, on the contrary, act in the same manner as therapeutic inoculation and raise the opsonic index.

If the pus of a tuberculous abscess be centrifuged the fluid part will be found to be practically devoid of opsonins, although the circulating blood may contain a quantity of opsonins which is normal, or very little below. The presence of this inert fluid has probably by its mechanical pressure prevented the flow of lymph through the abscess wall and its immediate neighbourhood. With its disappearance the parts have been flushed with lymph charged with bactericidal substances. Here we have the explanation of many clinical facts which before were inexplicable. Many years ago it was noted that patients who were the subjects of tuberculous peritonitis recovered after merely an exploratory laparotomy, during which the fluid contained in the peritoneal sac was allowed to escape, and cases were reported of recovery after paracentesis abdominis only. Every surgeon probably has records of cases of tuberculous peritonitis in which the happiest results have followed mere incision and lavage of the abdominal cavity. Two such cases I have seen or heard of lately in which I had operated upon the patients in 1904.

One of the patients, a boy, aged 13 years, was brought into St. Mary's Hospital on August 11th, 1904, with abdominal pain and distension. According to the history given the condition had only been present for four days and he had been walking about up to the time of his admission. The amount of fluid in the abdomen, and the absence of any serious symptoms of acute abdominal disease, suggested the possibility of tuberculous peritonitis, and this proved to be the case when the abdomen was opened. The peritoneal

cavity contained a quantity of yellowish fluid in which were floating flakes of soft lymph; the parietal peritoneum, the omentum, and the surface of the viscera were studded with numerous tubercles, of sizes varying from that of a pin's head to that of a grain of sago. The abdomen was well flushed out with sterile saline solution and was carefully stitched up in layers. The boy left the hospital in three weeks' time in apparently good health. I saw him the other day, over 18 months after the operation, and found him to be a well-developed, sturdy boy, looking considerably over 15 years of age and well over 10 stones in weight. He had not had any sign or symptom of a return of the condition for which he came into hospital and would now be regarded as a well-grown and vigorous youth.

The other patient was a youth, aged 17 years, who was admitted to hospital on August 29th, 1904. He had been taken ill 14 days before admission and he presented similar symptoms and appearances to those which were present in the last case. The peritoneum also contained a quantity of fluid, with flakes of lymph, while the whole peritoneal surface was practically lined by innumerable tubercles. The fluid was allowed to escape and the abdominal cavity was washed out. The patient left the hospital and I had not heard of him until the other day when, in response to a letter from me, he wrote to the effect that he had never had any return of the condition for which he came to hospital, that he was in good health, and had been able to follow his occupation. (In this case Sir A. E. Wright made an examination of the patient's blood and peritoneal fluid with the following results: patient's blood = 25.4 bacteria per cell; patient's peritoneal fluid = 4.6 per cell; A. E. W.'s blood, 17.0 per cell; the opsonic index of patient's blood = 1.5; peritoneal fluid = six times less.)

I do not intend to weary you this afternoon with a long recital of cases but I have mentioned these two to demonstrate the fact that a very extensive invasion of tubercle can be cured merely by the liberation under aseptic conditions of the inert material which had gradually accumulated without the employment of any chemicals or drainage, reliance being placed only on the flushing of the infected area by the normal fluids of the body charged with their protective substances.

The question now arises whether the individual's resistance cannot be raised, apart from any question of inoculation, whether by natural or artificial processes. Of this there can be no question. The efficacy of fresh air and sunshine in the treatment of tubercle has always been realised but it is only of late years that their full benefits have been obtained and that the open-air treatment for tubercle has been carried out on properly organised lines and with a full appreciation of the importance of detail. There is not time for me to go into the whole question of the open-air treatment, except to comment on the fact that with all these new sanatoriums springing up around us for the open air treatment of pulmonary tuberculosis no adequate provision is being made for the open-air treatment of surgical tuberculosis. This is the more extraordinary when we reflect that this country at the end of the eighteenth century was the first to realise the importance of fresh air in the treatment of these affections and opened the Royal Sea-bathing Infirmary at Margate for the treatment of scrofula. Probably the treatment at Margate was not the "open-air treatment" in the modern acceptance of the term but it was a marked advance in the right direction and the hospital has attained a deservedly high reputation for the treatment of surgical tuberculous affections. Since then numerous hospitals have been built on the continent for the treatment of surgical tuberculosis in children where operative measures can be carried out side by side with properly organised open-air treatment. During the last few years a great impetus has been given to this form of treatment in America and in the American medical journals of the last few years are constant allusions to the opening of new open-air hospitals for the treatment of surgical tuberculosis in children. I need only mention two—namely, the Seaside Hospital at Coney Island, N.-w York, and a small hospital that was opened in December, 1904, on the Wellesley Hills, eight miles out of Boston. In these establishments the children live in open verandahs or in wooden buildings termed "shacks," which are so constructed with sliding doors that half of each side of the building can be open to the air at the same time. These doors are only closed for short periods in order that surgical dressings and other nursing details can be carried out and the children practically lie day and night in the

open air. At night use is made of flannel sleeping bags with woollen gloves and hoods, but it is stated how little the patients appear to regard the cold of even a rigorous New England winter. The results at these and other open-air hospitals have been most encouraging. Patients have improved in weight and colour, sinuses have closed, and enlarged glands have subsided. Perhaps the one fact that stands out even more saliently than others is that it is not so much a question of climate or of any special location as of pure air and sunshine. This is an important point to emphasise, as in the large proportion of cases suffering from surgical tubercle the question of expense prohibits the search after what is considered a suitable climate, and if climate is considered the important element in cure most patients would easily become discouraged. The only exception which I would make is the smoke-charged atmosphere of big cities, but even in most unpromising surroundings efforts have lately been made at some of our children's hospitals to utilise their roofs as what the Americans term "sun parlours." Probably the clearer atmosphere of New York city is more suitable for such therapeutic measures than our more murky surroundings in London, and in the *New York Medical Journal* of Feb. 24th of this year there is an interesting account of the marked improvement that has taken place in two bad cases of caries of the spine, with sinuses, in which the patients have been treated on the roof of the New York Orthopaedic Hospital. These two patients—boys, aged respectively 11 and four years—who had been steadily growing worse, with hectic temperature, constant pain, poor appetite, and loss of flesh, were placed on the roof in November, 1905, only being brought to the ward for dressing and nursing purposes. We have all seen such cases, and I only mention them here to show what can be done even in such unpromising environment as the surroundings of a city hospital. In most of our big towns, however, and certainly in London, I do not think that it is practicable to organise this open-air treatment on any extensive scale in the midst of the town itself. What is required is that at a convenient distance in the country (for it is not necessary to go to the sea) small hospitals should be built with facilities for open-air treatment. Such hospitals should be considered extensions or adjuncts of our big city hospitals, and to them cases of surgical tuberculosis should be transferred from the latter. Each hospital should be properly equipped for the performance of major surgical operations and these should be undertaken by the staff of the mother hospital. I consider this an important element in the scheme, as it is essential that such operations should be performed by those whose routine work leads them to the performance of major operations in all parts of the body and gives them facilities of manipulation and a skill in technique which could not perhaps be attained by anyone whose operative work was limited to these particular cases. I should not anticipate any difficulty in staffing these hospitals from among the members of the honorary staff of our metropolitan and provincial hospitals. Facilities of suburban transport and telephonic communication have enormously increased during the last few years; the operations would rarely be "urgencies," and could be performed on regular visiting days, and the visits would be distributed among the surgical staff of the general hospital, two or three doing duty for certain periods of time, so that no undue amount of work would devolve on any individual. Resident house surgeons would be responsible for the care of the cases in the absence of the honorary staff and on them also would devolve the routine blood examination and therapeutic inoculations under the guidance of the pathological department of the hospital.

I have only faintly outlined a scheme the details of which would no doubt vary in different localities, but I think it is of prime importance that such hospitals should be organised in conjunction with, and not independently of, our big general hospitals, and unless the managers of the latter take the initiative I am afraid that small independent hospitals will be multiplied, with the result of yet more examples of that waste of effort and overlapping which are so characteristic of charitable enterprise in this country. That such institutions will spring up in the next few years I feel confident, and now is the opportunity to secure some order in their organisation.

I have dwelt at some length on the importance of open air in the treatment of these cases and with this goes free access to sunlight. I do not wish to raise the whole question of light therapy which at present we scarcely understand.

The efficacy of sunlight in the treatment of all chronic infections has been realised from time immemorial, and lately the use of the Finzen light has brought the whole subject into prominence. Dr. Bulloch suggests that its efficacy depends upon its power of determining a flow of blood or lymph to the infected area in a manner that cannot be imitated by any other therapeutic agency and that the area in question is thus flushed with lymph carrying with it protective substances. Light therapy certainly appears to give the best results in those extremely chronic infections which would appear to be almost completely shut off from the general circulation of body fluids as judged by the absence of any general dissemination. The best example of such a condition is found in lupus, and it is to these cases that light therapy is peculiarly applicable.

Another therapeutic measure, of which, perhaps, insufficient use is made in the treatment of surgical tuberculosis, is massage, either general or local. General massage increases the circulation of tissue fluids and would be indicated in cases where a low opsonic index, with absence of pain and of rise of temperature, indicated a small amount of auto-inoculation. In addition, massage raises the muscular tone and improves the appetite.

The question of local massage is a more difficult one and the measure has a far more limited application. We have all seen glands in the neck breaking down under a vigorous course of massage at the hands of a mother or nurse and some of us have seen tuberculous joints red, swollen, and exquisitely tender as the result of a course of massage and movements prescribed under a misapprehension of the nature of the case. But has it ever occurred to us that, considering how common such methods of treatment are, these untoward results are comparatively rare and that we often meet with patients of whom it is said that they recovered in spite of such treatment? Local massage should be prescribed with the greatest caution, but I believe that in properly selected cases it has a definite therapeutic use. The chart which I now send round was prepared by Mr. J. Freeman, working

Even if local massage were never accepted as a therapeutic measure in the treatment of arthritic or glandular tubercle such a case as the one I have just quoted should make us ask ourselves the question whether the absolute fixity of the joint is indicated in every case of tuberculous arthritis or whether the lymph circulation could not be accelerated by carefully graduated movements. On the other hand, it cannot be emphasised too strongly that in cases where there is evidence of considerable auto-inoculation, with an opsonic curve marked by variations of some magnitude, not only should the limb be rigidly fixed but the patient should be kept lying down, and the circulation rendered as quiescent as possible. I believe this to be merely a scientific explanation of a well-established clinical observation.

The question of feeding is an important one, the essentials being a plentiful supply of easily assimilable food and the absence of any fresh infecting material. For this reason the milk-supply should be above suspicion and the dietary should contain a sufficiency of animal fats in an appetising and easily digestible form. Cod-liver oil is invaluable in these cases and is usually prescribed with iron or maltine, accordingly as there is difficulty or not in persuading the patient to take the oil, the latter combination being the more palatable.

I now pass on to the consideration of the operative measures available in these cases. The tendency of late years has certainly been towards conservatism, and we hear of fewer cases of excisions of joints, although there are still able advocates of the extirpation of tuberculous glands, on lines similar to those employed in the removal of glands secondary to cancer. In the circumstances at present existent in our large London hospitals there is much to be said in favour of such drastic treatment, but under more favourable surroundings more limited operations would be, and are, found sufficient.

The chief consideration in these operative procedures is the prevention of sepsis, and this becomes all the more important when we realise that asepsis is difficult of attainment in these cases. Healthy tissues are capable of dealing with a slight amount of contamination but tissues already the seat of microbic invasion are less resistant. It is difficult to lay sufficient stress on the effect of a secondary infection in a case of tuberculosis. Apart from the dangers peculiar to sepsis itself the secondary infection has a markedly unfavourable influence on the course of the original tuberculous process. This has long been a matter of clinical observation but was more scientifically demonstrated in 1904 by M. Petroff working in the Institut Pasteur.² This observer found that closed foci of surgical tuberculosis, which had not yet been subjected to surgical intervention and were covered by sound skin, were not, as a rule, associated with any aerobic or anaerobic organism other than tubercle, and this rule obtained even in those cases which presented signs of acute inflammation. (In 57 cases examined 49 did not give any development of germs, and seven of these showed acute symptoms. In the eight cases which gave positive results there were possibilities of infection owing to adjacent sinuses, excoriations of skin, &c.) Further, he found that open foci of surgical tuberculosis always contained associated microbes which were for the most part pyogenic cocci of feeble virulence. (In 44 cases examined 41 gave cultures of various organisms, 23 of staphylococcus—16 white and seven gold—18 of streptococcus, four of bacillus pyocyaneus, two of micrococcus tetragenus, and one of bacillus coli.) M. Petroff further inoculated pure cultures of tubercle and of tubercle mixed with other organisms into the two knees of a series of rabbits. In all cases where the secondary infection had a sufficiently long duration the examination of the parts showed more granulations and more destruction of the articular surfaces in the secondarily infected joints than in those infected with pure tubercle. In the former the epiphyses and bone were attacked but in the latter only the synovial membrane and ligaments. In another series of rabbits he demonstrated that the dissemination of the tubercle was markedly accelerated by secondary infection. This is partly accounted for by a weakening of the infected individual's resistance and partly due to changes produced in the local tuberculous process. The latter is a slow process and allows the host to wall off the invaded area with a barrier of granulations and this barrier may be broken down by an acute and destructive inflammation. The dissemination

Tuberculous knee: massage and injection.

in Sir A. E. Wright's laboratory, from observations on a patient of mine, and it will form part of a paper which Mr. Freeman will shortly publish on this particular subject.

The patient was a small boy with a definitely tuberculous knee-joint. The case was a chronic one, with swelling, only slight pain, and some flexion. He was kept in bed with a weight extension apparatus on the limb to overcome the flexion. The pain and flexion soon disappeared and an examination of his blood showed that his opsonic index was normal. On Dec. 5th, 1905, gentle massage was applied to the joint. The boy did not complain of pain and a few hours afterwards his opsonic index had risen to 1.3 and on the next day to 1.5. A few days later it was again normal. The experiment was repeated some three weeks later, when his index was below normal and it again rose to 1.3, falling again to below normal. Later, an injection of 17.5th milligramme of tuberculin was given and was followed by the usual negative and positive phases, the latter being maintained for some days.

This is only one case, but Mr. Freeman has other evidence that careful manipulations in such cases have very much the same results as a therapeutic inoculation. It is obvious, however, that the result of such measures should be carefully watched, as it would be comparatively easy to give an overdose or to superimpose one negative phase on another.

² Annales de l'Institut Pasteur, 1904, vol. xviii., p. 502.

took place by the blood stream, slowing itself first in the lungs. This is in accordance with our clinical experience that tubercle of joints does not cause enlargement of the lymphatic glands, but that dissemination, in the event of its occurrence, is shown by the onset of tuberculous meningitis or of general miliary tuberculosis. This experimental evidence explains the well-established clinical fact of the greater malignancy of open forms of tubercle as against closed.

Our chief aim therefore in dealing with tuberculous abscesses in connexion with bone disease is to prevent the formation of sinuses; and with this object I have for the last few years discarded the use of drainage-tubes after operating on such cases. This, however, cannot be done successfully unless there has been absolute asepsis during the operation and, in addition, the tissues have not been irritated by the use of chemicals. In order to secure this I recommend the use of rubber gloves for the surgeon, his assistant, and chief nurse during these operations. The abscess cavity is flushed out with sterile saline solution and any loose tuberculous sequestra are removed. Only a minimum of scraping appears to be necessary and this often resolves itself into merely wiping out the interior of the cavity with pieces of sterile gauze on holders. The wound is then closed, the deeper fascial structures being first sewn up with catgut. I consider this important, as in a few cases where only skin sutures were employed there was a secondary infection by tubercle of the deeper parts of the superficial wound with the subsequent formation of a sinus. In a fair proportion of cases the abscess cavity slowly refills, generally without any febrile reaction, and a second and occasionally a third operation may be necessary, the same process being repeated each time. Often months elapse before a second operation is necessary and, in a certain number of cases, the one operation is sufficient. I have recently seen a little boy on whom I operated in this way in January, 1904. His age was then four years and he was admitted for lameness which had been present for four months; his right thigh was slightly flexed and he was found to have a right iliac abscess. This was opened, flushed out, and the wound was closed. The original bone disease, which was probably in the upper sacral or lower lumbar spine, could not be demonstrated. The patient was discharged from hospital using a double Thomas's splint and he returned in three months with a recollection. This was dealt with in the same way and the boy, who lived in the northern suburbs of London, was kept on his back for 12 months, his mother placing him out of doors on some leads as often as she possibly could. He was lately brought to me for some trifling ailment and appeared to be perfectly well as regarded his sacral caries.

Now that we know more of the curative effect of the body fluids on tuberculous foci it appears to me to be unscientific to fill these cavities with iodoform emulsion or to attempt to disinfect the diseased area with such a chemical as pure carbolic acid. The object of the operative procedure should be to substitute healthy living body fluids charged with bactericidal substances in the place of the stagnant inert material removed. As far as possible I use the same procedure in the case of joints, always preferring an arthroscopy to an excision, the latter operation only being occasionally necessary in the case of adults. After a somewhat lengthy and extensive operation on a joint, and especially where gloves have not been worn for some reason and where there has been in consequence a good deal of "finger mashing," I consider it safer to leave a tube in for 24 hours with a loose stitch which can be tied on removing the former. Should further drainage than this be necessary I consider that I have failed in the object which I set myself.

In the cases of tuberculous adenitis a clean excision of the infected glands is still the best treatment, after a short trial has been given to constitutional treatment, on the lines already suggested. The possible postponement of the operation thus entailed would be amply compensated for by the fact that the operative and constitutional treatment would be carried out simultaneously and on the importance of this I have already laid stress.

I need scarcely discuss here the importance of dealing with such possible sources of sepsis in cervical adenitis as carious teeth, otorrhoea, impetigo of scalp, &c.

I would thus summarise the treatment of these cases of osseous, arthritic, and glandular tuberculosis. 1. In all cases "open-air treatment" should be organised to meet the circumstances and requirements of the particular case. 2. That

in every case the patient's powers of resistance to the disease should be periodically measured by suitable blood examination. 3. That, where the resistance is found low and there is no evidence of an excessive auto-inoculation, use should be made of therapeutic inoculations of Koch's new tuberculin in doses that are accurately controlled both as regards their amount and repetition by examination of the blood. 4. That in cases where there is evidence of excessive auto-inoculation absolute rest, with complete fixity of the diseased part, should be prescribed. 5. That in cases where it is evident that the diseased area is circumscribed and practically cut off from the circulation of tissue fluids efforts should be made to improve the circulation through the diseased area. The means we have at our disposal for this are fomentations, the use of certain mild irritants—e.g., liniment of iodine and Scott's dressing, light therapy, general massage, and local massage with carefully regulated movements. 6. That operative procedures should be directed to the removal of the dead, inert material, whether pieces of bone or collections of pus, and should be conducted with the most scrupulous aseptic precautions.

I have left myself but little time in which to discuss the important subject of genito-urinary tuberculosis. The most important recent advance in this particular branch of surgery has been in the improved means of diagnosis. By means of modern cystoscopy tubercle of the bladder and kidney may be diagnosed even before bacilli have appeared in the urine and constitutional treatment can therefore be adopted at an earlier stage with consequently greater hope of success. At a later period in the disease the condition of the second kidney in a case of renal tuberculosis can be ascertained with greater accuracy and there ought to be fewer of those surgical tragedies in which the less diseased of the two kidneys has been removed by the surgeon.

I feel that I have brought forward nothing that is original or new and that I have but touched the fringes of a large subject. I trust, however, that the experiences and views of other surgeons will fill in the gaps in this attempt on my part to collate the recent improvements of treatment of this important and ubiquitous disease.

Harley-street, W.

HINTS TO THE GENERAL PRACTITIONER ON EYE STRAIN AND ITS SYMPTOMS.¹

BY JAMES HINSHELWOOD, M.A., M.D. GLASG.,
SURGEON TO THE GLASGOW EYE INFIRMARY.

EYE strain as a cause of numerous symptoms has been gradually occupying a great share of the attention of the general practitioner. This, no doubt, is partly owing to increase of knowledge regarding the eye but is due also to the increasing demands made upon the organ of vision by the more exacting conditions of modern life as regards the amount of near work which most of us have to do from childhood upwards. Hence the victims of eye strain, owing to the stress of modern life, are more numerous than in past times and hence also the increasing importance to the general practitioner of being thoroughly familiar with the varied symptoms which this common condition may give rise to.

As we shall shortly see, the real cause of many symptoms produced by eye strain is frequently not suspected by the patients and therefore they have recourse for the relief of these in the first place to their family medical adviser and do not seek at first hand the aid of the specialist. Hence the importance to the practitioner of being familiar with the symptomatology of eye strain, as it will guide him to a correct diagnosis in such cases. Whilst correct diagnosis is always of great importance, here it is particularly so, as the recognition of the true character of the symptoms presented at once leads to their appropriate treatment and to their rapid and complete disappearance.

At first sight it seems very curious that the patients themselves, in a large proportion of cases, never suspect the eye

¹ A paper read at a meeting of the Glasgow Eastern Medical Society on March 7th, 1906.

as the cause of their sufferings. But on closer consideration the explanation of this apparent paradox, that a person should suffer from eye strain without being aware of it, is very easy. If eye strain always manifested itself by pain or discomfort in the eye its recognition would be easy. This, however, is not the case. In a very large number of cases of eye strain there is no pain whatever or discomfort of any kind in the eye, but the symptoms produced by it lie altogether outside of that organ and hence their true nature may be entirely unsuspected by the patient. Ocular headache is perhaps the best example of this. A patient may suffer from headache for many years without having the slightest suspicion that the real cause of the headache is to be found in the condition of the eye, because he is not conscious of any pain or discomfort in the eye itself. This is more especially the case when the headache is not near the eyes but at the top or back of the head, as it not infrequently is. The symptoms of eye strain may lie, therefore, altogether outside of the eye and hence their true nature may not be suspected by the patient and may even for a time baffle the diagnostic powers of the medical adviser unless he possesses a knowledge of them.

Another reason for the non-recognition of eye strain as a cause of symptoms is that the patient may not be aware of any failure of vision and hence attention is not directed to the eye. There are several causes for this. In the first place, the acuteness of vision may be perfect and yet the patient may be suffering severely from eye strain. Eye strain in its worst forms is met with in cases of hypermetropia and yet in many of these cases the visual acuity if tested with the distance types is absolutely normal. Hence any visual deficiency is often unsuspected by such patients, who often pride themselves on their "good sight" and feel at first rather indignant when the advisability of wearing glasses is suggested. The hypermetrope must use his accommodation for distance and with its aid he may be able to see quite well. This means, however, a constant strain upon the ciliary muscle which in these cases is never at rest. The accommodation is active in these patients from the moment they open their eyes in the morning until they close them in the evening and hence this constant muscular strain evidences itself by numerous discomforts, of which headache in some form is the most frequent. A further reason is that often the error of refraction which produces the eye strain and its attendant unpleasant symptoms may be very slight, so slight as to interfere very little with the acuteness of vision as made out by distance tests. We have the best examples of this in the case of astigmatism, where cases of eye strain are to be found more frequently in the low than in the high degrees. This, again, seems an apparent paradox but its explanation is easy.

In very high degrees of astigmatism the patient's vision is very defective and no efforts on his part can improve it to any appreciable extent and hence there is no constant strain upon the eye. In the very slight degrees of corneal astigmatism, which simply cause a slight amount of blurring, there is a continuous effort of the ciliary muscle to counter act or to diminish this corneal astigmatism by producing a lenticular astigmatism by irregular contraction of the ciliary muscle. It is this constant and continuous strain on the ciliary muscle that produces the distressing symptoms from which such patients often suffer. It is often almost incredible what great relief can be afforded to such patients by the prescription of a cylindrical glass of half or even quarter of a dioptre. The explanation of the relief afforded by the correction of such slight defects is to be found in the fact that such slight defects give rise to continuous strain and that their correction puts the eye in a condition of rest.

These facts about eye strain—viz., that the patients themselves may not be aware of it, that it may exist with normal visual acuity as tested with the distance types, and that it arises very frequently in the case of very slight errors of refraction, should be familiar to every practitioner.

It will be seen, also, from what has already been said that such defects can only be made out on the most careful examination. It is now my routine practice to examine most cases of suspected eye strain under the influence of a mydriatic, as the slighter cases may entirely escape observation unless this precaution is taken and the accommodation paralysed. When we are dealing with very small degrees of astigmatism it will be evident that the correction of this must be done with great precision and accuracy. No pains should be spared to arrive at the exact correction, because

anything short of this will have little effect in such cases. I have found in dealing with these cases that the mere subjective testing is at first not only unsatisfactory but often positively misleading, owing to spasms of the ciliary muscle due to the constant strain. Hence in my opinion the absolute necessity in many cases of paralyzing the ciliary muscle in order to obtain an idea of the static refraction of the eye. Besides, the rest to the eye for a couple of days under the influence of homatropine is most favourable to the subjective testing which is necessary at a later visit.

I wish to emphasize the point that the prescription of suitable glasses in these cases of eye strain due to slight astigmatism is a proceeding of great delicacy, which can be successfully accomplished only by the specialist with a large experience of the peculiarities and idiosyncrasies of the human eye, and even this sometimes only with great patience and perseverance. The presumption of opticians seeking to deal with such cases is as absurd as that of the chemist who seeks not only to supply his customers with drugs but also to diagnose and to treat their ailments. The eye is an exceedingly delicate organ and immense damage is done by the prescription of glasses by those who are not properly qualified for the task. Every ophthalmic surgeon has experience of this and the practitioner should clearly understand that an optician cannot possibly have the requisite knowledge for dealing successfully with the very delicate, and often very difficult, problems which cases of eye strain frequently present.

It is often a matter of great difficulty even to ophthalmic surgeons of large experience to discriminate between symptoms due to refractive error and those due to early stages of organic disease of the eye. A mistake in the diagnosis may lead to most disastrous results to the patient and yet the public are invited to intrust the care of this most delicate of all organs into the hands of those who know absolutely nothing about the symptoms of disease in the eye or elsewhere. Let the medical profession beware of encouraging the public in the fallacy that the optician can distinguish between symptoms due to refractive error and those due to disease. This can be done only by those with a competent knowledge and long experience in diseases of the eye.

Let us now pass briefly in review the chief symptoms caused by eye strain. We may divide these into two classes: (1) the local symptoms, those having reference to the eye itself and its appendages; and (2) those occurring outside the organ itself, the general symptoms. We will begin with the second group, as these are the symptoms which are frequently not recognised as of ocular origin. The most frequent symptom of this group is headache.

The greater my experience of ophthalmic practice the more I am impressed with the frequency of eye strain as a cause of headache. For reasons already stated the true cause of the headache may have been suspected neither by the patient nor by the medical attendant. I saw six months ago a woman, aged 60 years, who for about 40 years had been greatly troubled with headache to such an extent that, as she expressed it, her life was more or less a misery. She came to me because she was not seeing so well with her glasses, which had been prescribed by an optician, but she had no suspicion that her headaches were due to eye strain. I found that she had a moderate amount of astigmatism which had never been corrected. I insisted that she should wear cylindrical glasses constantly and the cylinders combined with sphericals for close work. It was with great difficulty I could persuade her to wear the cylinders constantly, since she said she did not feel that she required them, having fair distant vision. This is often the great difficulty with such patients. I explained, however, that the distance glasses were prescribed not to make her see a great deal better but to put the eyes in a position of rest and to relieve her from eye strain. She wisely followed my advice with the result of the complete disappearance of her headaches, very much to her surprise. Here was a patient whose life had been rendered miserable by 40 years of headaches, which could have been completely relieved by the constant wearing of suitable glasses. Here was a case of pure ocular headache. Its true cause had never been suspected either by the patient herself or by the medical men she had consulted with regard to it because there was absolutely no discomfort in the eyes and because the patient thought that she had good distant vision. This is a striking example of what I am very frequently seeing. Hence, every medical man may take it as

a very safe rule that in every case of chronic headache which does not yield to medical treatment the eyes should be carefully examined, even though the patient protests that he has excellent vision.

I would here call special attention to the fact, not so generally known as it ought to be, that in many cases headache is due not to a single cause but to a number of different factors, each of which must be removed before the patient can get rid of the headache. Failure to recognise this clinical fact is often the cause of the failure to give the patient relief. Eye strain in such cases is often an important contributing factor but the relief of the eye strain will not cure the headaches until all the other contributing factors have been dealt with. When a patient complains to me of headache being present the moment he opens his eyes but getting gradually worse as the day goes on then I regard it not as a simple ocular headache but as a headache of complex character, towards the production of which eye strain may be an important contributing factor but cannot possibly be the sole cause, otherwise there would be no headache after a good night's sleep. There may be other contributing causes, such as anæmia, constipation, and dyspepsia, which of themselves give rise to toxic headaches and when combined with eye strain render them of greater intensity. But if we are to get rid completely of the headaches we must deal not only with the eye strain but also with the anæmia, or constipation, or dyspepsia. Every contributing factor must be removed.

Ocular headache may occupy any position. Most frequently it is frontal but it may be vertical, occipital, and sometimes I have noted pain at the back of the neck due to eye strain. It may be constant or may come on in attacks of more or less acuteness with intervals of freedom. As a rule, ocular headaches are relieved by sleep and become more intense as the day goes on. Even attacks of megrim or sick headache with retching and vomiting may be caused by eye strain.

I have elsewhere discussed this subject in much greater detail and those who wish to gain a more precise knowledge of this distressing symptom I would refer to my papers on Ocular Headache, in the *Glasgow Medical Journal* for November, 1900, and on Chronic Headache in the same journal for January, 1904.

Apart from headache there are often very peculiar uncomfortable sensations in the head complained of by persons suffering from eye strain. A sense of fulness in the head and sense of tightness are sensations often complained of by patients suffering from eye strain and are permanently relieved by the constant wearing of suitable glasses. Giddiness is another familiar though less frequent symptom of eye strain. Eye strain is not a common cause of giddiness but still it should always be borne in mind when it cannot be traced to the more common causes, such as nervous disease, gastric disorder, or aural disease, and the patient's refraction should be carefully examined. As this symptom is frequently also found in muscular asthenopia, probably due to the consequent diplopia, the condition of the ocular muscles must be carefully investigated and suitable prisms prescribed if there is a lack of muscular balance.

I have seen many examples of giddiness relieved by the prescription of suitable glasses. About a year ago I saw a man who for many years had suffered from giddiness. At first it was thought to be due to locomotor ataxia and subsequently to cerebellar diseases as it was so distressing. The non-development of further symptoms led to the abandonment of this diagnosis. The patient observing that the attacks were worse after much use of the eyes consulted me. He was suffering from a high degree of hypermetropia and suitable glasses were prescribed for constant wear. The patient is now completely free from the vertigo which made him miserable for years. The vertigo was purely ocular and disappeared when the eye strain was removed.

Insomnia is not a common result of eye strain but it is sometimes met with and hence should always be thought of as a possible cause. More especially should it be suspected in the case of individuals who use their eyes a great deal. Severe eye strain produces as we shall see congestion of the vessels of the eye and lids and I have no doubt also some degree of cerebral congestion. Hence frequently the cause of the headache and of the sense of fulness and tightness in the head complained of so often in cases of eye strain. This cerebral congestion is probably also the cause of the insomnia sometimes met with in severe cases of eye strain. I have met with several cases of insomnia in students with

errors of refraction and as the insomnia permanently disappeared on the prescription of suitable glasses there could be little doubt that eye strain had been the cause of it. The most striking case which I have seen was that of a tailor who was also of a literary turn and after a continuous day's labour with the needle he spent his evenings over books. He had been taking sulphonal and other hypnotics for years. He was astigmatic and after the wearing of suitable cylindrical glasses he was able to dispense with the hypnotics which he had been previously using.

There are certain local symptoms also in the eye and its appendages which frequently furnish the evidence of eye strain. Eye strain produces a congestion of the eye itself and of the eyelids. Hence a great number of cases of chronic conjunctivitis and especially chronic blepharitis or inflammation of the edges of the eyelids are directly due to eye strain. The use of lotions and ointments may help to modify these conditions but cure is impossible until the cause is removed by the relief of the eye strain. Hence in all obstinate cases of conjunctivitis and blepharitis which resist ordinary treatment the refraction of the eyes should always be very carefully examined, as refractive error may be the primary cause of the mischief. The chronic congestion of the conjunctiva and edges of the lids, which makes a person look as if he had been weeping and is a source of considerable disfigurement, is often due to eye strain. All local treatment is of little avail in reducing this chronic congestion of conjunctiva and lids until the patient is wearing appropriate glasses and the eye strain is relieved. I have seen also many cases where the patients were troubled with persistently recurring crops of "styes" until the discovery and correction of some refractive error put an end to this troublesome affection.

Nictitation or blinking caused by spasmodic contractions of the orbicularis muscle is a symptom which is sometimes the result of eye strain and often the first symptom which calls attention to the condition of the patient's eyes. I have seen this symptom as the result of eye strain more especially in the case of children. When the result of eye strain it gradually disappears under the regular use of atropine which puts the eye into a condition of rest. This is the first step in the treatment of those cases—viz., to keep the eye thoroughly under the influence of atropine for a few weeks until the blinking has completely disappeared. Then suitable glasses are to be prescribed for constant wear, correcting the error of refraction before the patient is allowed to use the eyes again.

The forms of eye strain which we have hitherto been dealing with are due to muscular strain, either ciliary strain, generally called accommodative asthenopia due to strain of the ciliary muscle or muscular asthenopia due to strain of the extrinsic muscles of the eye, of which strain of the internal recti or convergence strain is the commonest form.

There is another form of eye strain—viz., retinal asthenopia—which though much less frequent than the muscular forms is by no means rare and is often exceedingly troublesome to get rid of. In this condition the retina is hypersensitive and is very easily exhausted. There is a great sensitiveness to light sometimes amounting to photophobia, and there is usually some degree of pain in the eye or at the back of the eyes. There may also be some degree of conjunctival hyperæmia, associated with more or less lachrymation. This retinal hyperæsthesia, as I call it, may or may not be associated with a refractive error. When associated with a refractive error it is found that glasses give little or no relief. In fact, the wearing of glasses in these cases seems to intensify the patient's sufferings. I have seen this more especially in cases of myopia. The wearing of the concave glasses in such cases increases greatly the patient's discomforts, because the very increase in the distinctness of the images thrown on the retina seems always to irritate it. Hence in many of these cases, even with errors of refraction, I often insist upon the patient laying aside glasses altogether for a time. I do this especially in myopic cases, where the laying aside of the glasses, though diminishing the visual acuity, does not mean any increased muscular strain. Great harm is often done in such cases by the patients having been advised to wear glasses constantly, which by increasing the brightness and distinctness of the images still further exhausts the retina and increases the suffering and discomforts of the patient.

Such retinal asthenopia is often met with in neurasthenic conditions of the nervous system, the retina sharing in the

general neurasthenia, and hence the treatment must be chiefly directed to the improvement of the condition of the patient's nervous system. In many cases it is associated with a general toxic condition such as is met with in constipation and dyspepsia and is probably due to defective nutrition of the retina owing to the toxic condition of the blood. In such cases, also, the treatment of the general health of the patient is all important and only when the patient's general health is brought into a satisfactory condition will the retinal asthenopia disappear. Local treatment, such as rest, protection from bright light, and the use of ocular analgesics, such as holocaine and dionine, will give a certain measure of relief to the sufferings of the patient, but the removal of the asthenopia and the ability of the patient to use the eyes will only be accomplished by improvement in the general health of the patient and until this is effected the asthenopia will continue in spite of all local measures. The removal of the varied symptoms due to muscular eye strain will be successfully accomplished by the prescription of suitable glasses and by intelligent care in the use of the eyes.

In many cases it will be necessary for the patient to wear glasses constantly even apart from near work. This is the part of the treatment which it is often very difficult to get the patient to comply with and yet is often most essential for the removal of the symptoms of eye strain. A patient with hypermetropia or astigmatism is constantly using his accommodation even for distance, hence the eye rapidly gets into a fatigued condition and is unable to accomplish without discomfort the farther effort required for close work. If the hypermetropia or astigmatism be corrected and the lens constantly worn the eye is now in a position of rest and may be able to respond to the increased effort required by near work. The patient must be made clearly to understand that the distance glass is to be worn constantly, not in order to make him see more clearly but in order to make him see with less effort and keep the eye in a position of rest. In a very large number of cases of eye strain this is the all important point in their successful treatment and it is the point of the treatment which it is very often difficult to get the patient to adopt owing to the irrational prejudice in many minds against the constant wearing of glasses. Further assistance may be given if necessary by prescribing a special glass for near work and this I do in a large number of cases, even in young people, who are using their eyes much for near work. The object to be aimed at in cases of eye strain is to enable the patient to exercise the functions of vision with a minimum of exertion on the part of the eye.

Another part of the treatment quite as important as the wearing of glasses is intelligent care in the use of the eyes. I saw a patient a short time ago who was suffering from eye strain and who informed me that he was using his eyes for fine work for nearly 17 hours a day. There was no error of refraction whatever and the discomforts complained of by the patient were simply due to overtaxing the eyes—a condition which no spectacles could ameliorate. People must be taught that the eye can be overwrought and that it is only capable of accomplishing a certain amount of near work with comfort to the individual. I have often given people great relief by curtailing the amount of near work or by advising them to take periods of rest and not to work the eye too continuously for long periods of time.

Great benefit may also be derived by being careful to avoid exerting the eyes excessively in looking at very minute objects. Ladies suffering from eye strain I always advise for a time to abandon any fine sewing and rather to take to knitting, which being largely accomplished by the sense of touch does not throw anything like the same strain upon the eyes. Those who are fond of reading I specially request to use only books which have large and clear type. I often refer my patients to Lord Rosebery's "Napoleon," published by Humphreys of London, as a model of what a printed book ought to be, dull paper, thick black letters of good size, with ample room between the individual letters and the lines. A book printed in this way means a minimum of exertion to the eye. In the case of children this is of very special importance. Much greater attention has been given to this of recent years by the publishers of children's books. The series of school books published by Messrs. William Collins, Sons, and Co., "Collins' Clear Type Press," deserve special commendation as in the clearness and blackness of the type, the size of the letters, and the large spacing they form models of what such books ought to be and confer a real benefit on the rising generation of school children. Care with regard to proper illumination is also of importance

in cases of eye strain. The light should be good and not too intense. The greatest care should be exercised that whilst the book or object looked at is well illuminated the eyes themselves should be in the shadow and not exposed to the direct rays of light. Hence the light should be coming from a source behind, at the side, or above. The source of light should never be in front, as the rays of light entering the eyes directly fatigue the retina and so lead to eye strain. I have seen children suffer a great deal with their eyes from being placed at school with their faces to a large window all day long instead of with their backs to it. When the position of the lighting was altered their symptoms disappeared.

In the treatment of eye strain it is therefore important to impress on the patient that more is required than the prescription of suitable glasses. The patient must be instructed to use his eyes in an intelligent way so as to throw a minimum of strain upon them and allow the function of vision to be exercised under the most favourable conditions. Attention must be given to the length of time the eyes are used for near work, to the size of the objects looked at, and to proper illumination. The intelligent cooperation of the patient is necessary in such cases to bring about a satisfactory result. Any local affections of the lids, the passages, or of the eye itself of course require careful treatment. A patient will not be able to use his eyes with comfort until all pathological conditions of the eye itself, of the lids, and the tear passages have been removed.

Glasgow.

THE ORIGIN OF CHOANAL POLYPI.

By GUSTAV KILLIAN, M.D.,
PROFESSOR OF LARYNGOLOGY AND RHINOLOGY, UNIVERSITY OF
FREIBURG IN BREISGAU.

AMONG nasal polypi the so-called choanal or benign nasopharyngeal polyp occupies a special place. This has already been emphasised by Moldenhauer and lately Gerber has confirmed it. My own experience, which extends over 22 cases, also coincides. Choanal polypi are usually unilateral and solitary. They have a peculiar pear-shaped form, the broad end lying in the naso-pharynx whilst the stalk extends some distance into the nose. In the thick part of the polypus there is usually a large cystic space. This may be prolonged far into the stalk or the stalk may consist of nothing more than the thin wall of a particular cyst, which may, of course, be ruptured in the process of extraction. Once I observed a distinct groove of constriction where the pear-shaped part of the polypus passes into the stalk. Choanal polypi are characterised by the considerable size which they may attain. They are subject occasionally to inflammatory changes (according to my experience in 14 per cent. of the cases) which may terminate in partial or total gangrene. Spontaneous rupture of the cystic spaces in the polyp and spontaneous expulsion of the whole mass have been observed.

In microscopical structure these polypi hardly differ from the ordinary nasal polyp. The surface of the part lying in the naso-pharynx is usually pretty firm, of a whitish appearance, with flattened epithelial covering. The tissue of the tumour is composed of loose oedematous connective tissue. The cysts take their origin from large collections within the trabeculae and are therefore not clothed with epithelium. If the polyp inflames it becomes very red, swollen, and covered with fetid purulent mucus and at points with false membrane. The tissue contains hemorrhagic extravasations and is infiltrated freely with round cells.

From the point of view of treatment choanal polypi are very favourable. They may be laid hold of in various ways and readily torn out on account of their slender stalk. In the process the cyst in the body of the polyp, as a rule, bursts and I have observed immediately after the extraction, more particularly if the head be bent forward, a large quantity of sanguineous, serous fluid come away. In the majority of cases the polyp do not recur. The examination of the maxillary antrum shows in a series of cases a chronic inflammation of slight degree, with simple mucus, rarely purulent secretion.

Whoever glances through the literature of these peculiar growths will be struck by the fact that the views upon the

origin of choanal polypi are extraordinarily varied and indefinite. Usually the region of the choanae is regarded as the point of origin. A number of observers have stated that they come from the middle meatus but without committing themselves definitely to the exact point of origin. Moldenhauer thinks that they usually originate laterally in the upper part of the posterior end of the middle turbinal.

My own interest in the question of the origin of the polyp described above took shape when two years ago I sought in vain, assisted by all the diagnostic aids recently placed at our disposal, for the origin of the polypus in a typical case. Even by means of median rhinoscopy, which has done me most excellent service in the examination of the nasal fossae, no spot was found which could be regarded as the base of the polyp in question. I found in this case the accessory opening of the maxillary antrum unusually large and came to the conclusion that the polyp might have had its root within that cavity. The close observation of seven more cases enabled me to regard this as a definitely established fact of general application.

Anyone who wishes to convince himself of this should, in the first place, make as careful an examination as possible before the removal of the polypus, which for the most part is carried out in a hurried manner. The long nasal speculum should be introduced into the middle meatus, previously well cocaineised, and the middle turbinal firmly pressed towards the septum. After cleansing the field of view the stalk of the polyp will be seen to disappear laterally behind the region of the uncinate process. By means of a nasal probe bent forwards at right angles the observer may succeed by following the stalk in entering the maxillary sinus through an accessory antral opening. By drawing the hook of the probe against the anterior edge of this opening, laying it against the posterior edge, and following the upper and lower margins, the great width of the accessory opening may be determined with ease in these cases. This width can be definitely measured by marking the relative position of the anterior and posterior margin of the ostium to the external nasal entrance. I have found it to be from 1.7 to 2.2 centimetres.

For further observations on the antral origin of the polyp in question I recommend their extraction to be carried out with the cold snare. The wire loop is passed over the body of the polyp, slowly tightened, and laid close up to the spot where the stalk comes out of the antrum. The process of snaring is carefully done so that the stalk is not cut through. Then the polypus is torn out. By such a procedure the length of that part of the stalk lying inside the antral cavity may be determined with exactitude. I have found it from three to four centimetres long. It may be almost as long as the rest of the polyp. In the extraction of the mass a certain resistance is felt. As a rule, in the first place the cyst in the naso-pharyngeal portion of the polyp ruptures and discharges a large quantity of fluid. Further traction tears the polyp away suddenly.

I explain the resistance so clearly felt during the extraction in this way, that the portion lying inside the antrum is not by any means so thin as it appears after extraction but is swollen up by cystic fluid inside that cavity, in the same way as the body of the polyp. In extraction this thick intramaxillary part is pulled through the (in spite of its absolute width) relatively narrow ostium into the nose. This, of course, crushes the intramaxillary portion and its cyst ruptures. The cystic fluid falls into the empty antrum. The stalk is found to consist of a collapsed cyst wall. The fluid left in the antrum comes away later, especially when the head is held in a particular position, as already mentioned. It is obvious that the groove of constriction which I have observed in the stalk of the polyp is caused by the edge of the accessory ostium. Choanal polypi must in reality all have the form of a constricted sac, of which the one half is in the antrum and the other in the nose and naso-pharynx. We distinguish, therefore, a maxillary from a naso-pharyngeal part.

In further support of the maxillary origin of the choanal polypus it may be stated that on one occasion I saw the torn stalk project out of the accessory antral opening. In another case the remains of the polypus stalk within the antrum could be seen by means of a small mirror introduced into the middle meatus. Such cases would form suitable objects for investigation with the antroscope. It is to be hoped that with this instrument still more definite conclusions upon the actual point of origin within the antrum may be obtained.

The fact that the choanal polypi originate within the

antrum of Highmore explains their general and especially also their clinical behaviour. At first there is apparently a simple antral polypus. Part of this, occasionally as a result of blowing the nose, finds its way through the wide accessory opening into the middle meatus. A parallel to this is the observation that by inflation and irrigation of the antrum through the accessory ostium a polypus is occasionally driven out of the cavity into the nose as mentioned by Grünwald and Hajek. If a slender antral polyp gets caught in the ostium and fixed there we have the conditions present for its further development into a regular choanal polyp. In the first place a high degree of congestion must take place in the nasal portion. Hence the polyp grows pretty rapidly. In the posterior half of the middle meatus it finds but little room and here the slender part of its body is formed. When it reaches the naso-pharynx it may without hindrance attain considerable size, but the circulatory conditions are already so hampered that it tends less to new tissue formation than to collections of fluid within the meshes of the tissue, so that the formation of large cysts in the naso-pharyngeal portion is the result. It can scarcely be doubted that the growing stalk of the polypus presses in its turn upon the walls of the accessory ostium and widens this entrance. Under certain conditions, perhaps as the result of an acute catarrh, marked constriction of the polypus stalk within the accessory opening supervenes. As a consequence we have the appearances of inflammation, and redness, swelling, blood extravasations, &c., which may proceed to partial and total gangrene and even to spontaneous expulsion of the naso-pharyngeal portion.

The history of the development of the solitary choanal polypus leads back to the origin of antral polypi. That these owe their origin to inflammation of the antral mucous membrane is generally admitted. A case recently observed by me is especially instructive in this connexion and is of all the more interest here because it demonstrates the entire developmental history of a choanal polypus. I observed in this case two years ago a simple acute maxillary sinusitis with citron-yellow, glassy, mucous secretion, which rapidly healed after several irrigations. Examination showed a year later nothing particular in the nose and middle meatus. A short time ago, after the lapse of about a year, the patient in question came to me with a typical choanal polypus which had its root in the antrum formerly affected.

It may be mentioned that all stages from the antral polypus to the fully formed naso-pharyngeal polypus may occasionally be observed. Once I saw two polypi project out of the accessory ostium. In the numerous cases in which the nasal cavities are filled with polypi instances often come under notice which are like typical choanal polypi. As a curiosity I may mention a case in which a solitary naso-maxillary polypus had an angiomatous structure.

Changes analogous to those in the region of the accessory antral opening may also, of course, be observed about the opening of other accessory sinuses, and polypi which have developed within these sinuses may protrude through the openings into the nasal cavities and there take on further growth. There is no doubt that a polypus springing from a posterior ethmoidal cell or the sphenoidal sinus may in rare cases be transformed into a choanal polypus which can be distinguished from the majority of the above-described maxillary choanal polypi only by the most careful examination of the origin, especially before extraction. Zuckerkandl has given pictures of such cases. We find in his book illustrations of polypi which had grown with long stalks out of the antrum through the accessory ostium into the nose. In the literature of the subject I find the interesting statement that Palfyn (1753) had already observed such a case.

Freiburg.

MEDICAL MAGISTRATE.—Mr. Robert Roxburgh, M.B. Edin., F.R.C.S. Edin., of Weston-super-Mare, has been placed on the commission of the peace for the county of Somerset.

SOMERSET COUNTY COUNCIL AND THE TRAINING OF MIDWIVES.—At a meeting of the Somerset county council held at Taunton it was decided to make a special grant of £150 to the Somerset County Nursing Association for the training of six nurse-midwives who would be willing to work for the association in the county of Somerset for a term of at least three years after the conclusion of their training.

BUBOES AND THEIR SIGNIFICANCE IN PLAGUE.

BY WILLIAM HUNTER, M.B., C.M. ABERD.,
GOVERNMENT BACTERIOLOGIST, HONG-KONG.

THE occurrence of swellings in certain regions of the body is one of the commonest accompaniments of plague. The term "bubo" has been used so frequently and loosely in connexion with plague that the disease has generally become known, amongst the laity at least, as "bubonic plague." Why such an adjective should be constantly prefixed to the actual name of the disease is not clear and is certainly not based upon accurate scientific information. The presence of buboes is one of the most constant and at the same time one of the characteristic phenomena of certain types of the disease, yet when we review the whole history of plague as a dreadful "pest" it is found that so-called bubonic plague is by no means the most horrible manifestation of the disease and never occasions such devastation of life as other prominent forms of the disease, such as primary pneumonic plague. In fact, one might go so far as to describe ordinary bubonic plague as the more benign type of the disease, the malignant type being represented by primary pneumonic plague. Much has been written in regard to these bubonic swellings and from the voluminous literature on the subject one would conclude that almost the last word had been spoken in regard to this pathological lesion. Taking up the question from the standpoint of our present-day conceptions of bubonic plague, however, there would appear to be still many points wanting to complete the chapter dealing with such manifestations of plague and the true interpretation of their presence.

For the past four years I have been keenly alive to the presence of buboes and have noted many interesting points in regard to their pathological history and have endeavoured to adduce certain evidence in regard to their presence in plague. It is not my intention to enter into a deeply scientific description of the pathological appearances of buboes. Such is already well known. I wish, however, to bring forward my experience in regard to the anatomy of such swellings, the time of their appearance, their growth, their situation, their number, and subsequently to offer certain considerations regarding their origin in the disease.

1. *Their anatomy.*—The neck, the axilla, and the region of the groin are the commonest sites of these bubonic swellings. Their anatomy varies in these situations according to their severity. Occasionally it is only an enlarged gland with cortical injection; in other cases, however, the lesion may be widely spread, affecting structures placed at some distance from its focus of origin.

(a) *The neck.*—Buboes occur most frequently in the sub-maxillary, submental, supra- and infra-clavicular, sub- and retro-auricular, and parotid regions. The skin over the swollen mass is thickened and frequently covered with petechiæ. On section the mass is oedematous and hæmorrhagic. This appearance is not equally intense throughout. The glands are swollen and injected and imbedded in a densely infiltrated hæmorrhagic mass of connective tissue. The hæmorrhagic infiltration extends along the connective tissue spaces and surrounds the neighbouring muscles and other structures.

(b) *The axilla.*—The lymphatic glands and surrounding connective tissue form a soft oedematous mass of varying size. The super-adjacent skin is frequently covered with petechiæ. The oedema and hæmorrhage extend into the surrounding tissues to the scapular muscles, the pectoral muscles, the intercostals, down the arm, and up into the region of the neck. The breast in well-developed females occasionally participates and forms part of the bubonic swelling (bubo paramammario-axillaris.)

(c) *The groin.*—The swelling may be femoral or inguinal, or both, with extensions to the iliac and lumbar regions. The latter is common. The skin over the swelling is frequently covered with petechiæ. The hæmorrhagic and oedematous infiltration may extend down the thigh to the popliteal region or upwards over the lower part of the abdominal wall, into the scrotum, under Poupart's ligament into the pelvis, and spread over the belly of the ilio-psoas muscle, imbedding the iliac glands and the lymphatic

duct and cystema chyli, with extensions to the kidney, the pancreas, and even the diaphragm.

Apart from these three situations buboes may occasionally be found in the region of the tonsil, the popliteal space, the cubital gland, the sacral region, the mesentery, and the lymphatic glands around the coeliac plexus, posterior to the liver, and about the pancreas.

2. *Date of onset.*—This varies extremely. Buboes may be one of the earliest signs of plague. In my opinion they do not appear until certain prodromal symptoms have shown themselves. Many appear within 48 hours of the onset of the fever. In other cases their appearance may be delayed for several days. Cases have been reported where the bubo or buboes did not appear until the eighth, ninth, or tenth day of the disease. The majority, however, are well marked before the fourth or fifth day of the illness.

3. *Their growth.*—This is usually slowly progressive. In a few cases it would appear to be absent for some days and followed by a sudden and rapid increase in dimensions. This is frequently observed in buboes which have been late in appearing. According to Lawson, the prognosis is grave in such cases. Buboes are very variable in size; they may become as large as pigeon's eggs or a man's fist, or even larger. At other times the swelling never reaches a greater size than a hazel nut.

4. *Their situation and number.*—The results of the post-mortem examination of 1000 cases of bubonic plague are as follows:—

<i>Single buboes—</i>	
Right femoral bubo	289
Left " "	289
Right axillary " "	168
Left " "	129
Right inguinal " "	34
Left " "	24
Right cervical " "	22
Left " "	19
Left parotid " "	2
Right " "	1
Left sub-maxillary bubo	2
Right iliac " "	1-980
<i>Double buboes—</i>	
Right and left femoral buboes	6
Right and left axillary " "	3
Right femoral and left axillary buboes	1
Left femoral and right axillary " "	1
Right femoral and left cervical " "	1
Left axillary and left cervical " "	1-12
<i>Multiple buboes</i>	8
Total cases	1000

The following is a description of the cases in which multiple buboes were found.

CASE 1.—A Chinese female, aged 30 years. Large buboes were found in the following situations: (1) below and inside Poupart's ligament on the left side; (2) at the junction of the internal and external iliac vessels on the right side; (3) in the mesentery at its root; and (4) in the superior mediastinum. There was no consolidation of the lungs. The woman was pregnant. A six months' foetus was extracted. Plague bacilli were found in the maternal placenta. The results of the bacteriological examination of the foetus were negative.

CASE 2.—A Chinese male, aged 35 years. The following buboes were found: (1) in the right inguinal region; (2) around the left external iliac glands; and (3) in the right axilla. In addition to this the whole of the subcutaneous tissue of the right inguinal and lower parts of the right and left lumbar and umbilical regions of the anterior abdominal wall was oedematous and densely infiltrated with blood. Numerous plague bacilli were found in this tissue. There was no evidence of injury. The infiltrated area did not appear to have any connexion with the buboes present.

CASE 3.—A Chinese male, aged 52 years. The following buboes were found: (1) immediately below the left ear; (2) just above the left clavicle; (3) in the right axilla; and (4) in the left axilla. There was no apparent connexion between Nos. 1 and 2. No. 4 had no connexion with No. 2. The mesentery contained a large quantity of extravasated blood in which the lymphatic glands were imbedded. These glands were enlarged, slightly oedematous, and showed cortical congestion. Every organ and tissue of the body teemed with plague bacilli.

CASE 4.—A Chinese female, aged 18 years. The following

buboes of the size of a pigeon's egg were found: (1) in the right axilla; (2) in the left axilla; and (3) around the left external iliac glands. The hæmorrhage around the iliac glands extended over the ilio-psoas muscle, ran along the common iliac vessel to the aorta, and was continued upwards to the point of entrance of the inferior vena cava into the thorax. The bacillus pestis was found all over the body. The woman was seven months pregnant. No plague bacilli were found in the fœtus.

CASE 5.—A Chinese female, aged 25 years, a prostitute. Buboes were found in the following regions: (1) in the right axilla; (2) in the right inguinal region; and (3) in the left inguinal region. The hæmorrhagic extravasation in the inguinal regions extended downwards to the vulva. The extravasation was found in the labia as well as around the anterior portion of the vagina. The epithelial lining of the vagina was hyperæmic and showed the presence of a few petechiæ. The portio vaginalis was studded with minute points of hæmorrhagic extravasation. The arbor vitæ of the cervix was in a similar condition. The cervix and corpus uteri were œdematous, with mural hæmorrhages. Hæmorrhages were also found in the ovaries and the folds of the broad ligament. There was little tendency on the part of the extravasation to travel along the iliac vessels. The pathological changes appeared to be more or less confined to the pelvis. Plague bacilli were found in all the organs of the body.

CASE 6.—A Chinese male, aged 40 years. The following buboes were found: (1) in the right axilla; (2) in the left axilla; and (3) at the root of the mesentery. The mesenteric lymphatic glands were imbedded in extravasated blood and œdematous tissue. The glands were enlarged, hyperæmic, and œdematous, and cortical hæmorrhages were numerous. In several commencing necrosis was found. This mass of bloody tissue was crowded with plague bacilli. The ileum of the small intestine was hyperæmic. Hæmorrhages of varying size had taken place into the submucous membrane of this part of the gut. The solitary follicles were enlarged to beyond the size of a pin's head. Many of these looked like hæmorrhagic points; others were surrounded by a deep zone of congestion. The other parts of the small intestine and the large gut were normal to the naked eye.

CASE 7.—A Portuguese male, aged 28 years. Buboes were found in the following situations: (1) in the left cervical region; (2) in the right iliac region; and (3) in the left iliac region. The bacillus pestis was found in large numbers in the heart blood and in each of the bubonic formations. The hæmorrhagic extravasation, extending from either iliac bubo, met over the lumbar vertebræ and extended upwards, involving the lumbar regions and both kidneys, coming to an end just above the pancreas.

CASE 8.—A Chinese male, aged 30 years. Buboes were found in the following situations: (1) in the right femoral region; (2) in the right axillary region; and (3) in the left axillary region. The bacillus pestis was present in large numbers in each of these buboes. Large hæmorrhagic extravasations were found in the mesentery and around the cœliac plexus.

These cases of multiple bubonic formation are of great interest and point to the conclusion that plague is *ab initio* a disease of a septicæmic nature. If we allow this premiss, then the bubonic formations must be regarded as occurring secondary to blood infection. Buboes may appear early in plague. In fact, they may be existent before many definite symptoms of the disease are present. In other cases they appear late, during the course of a well-defined case of septicæmic plague. The reasons for this variability in the time of their appearance are by no means obvious. Again, such a swelling may be single, double, or multiple, without a satisfactory explanation of the process at work being evident. It has been my experience to find general lymphatic enlargement in ordinary bubonic plague. The glands are moderately increased in size, œdematous, and show extravasations of blood, especially in the cortical layers. Not only is this general enlargement of the glands found in bubonic plague but it is met with in cases of other types of the disease. In the purely septicæmic type this enlargement is one of the commonest changes found post mortem. In the pneumonic form—i.e., secondary lung plague—the glands are also similarly affected. In primary pneumonic plague hyperæmia and petechial hæmorrhages occur in the lymphatic glands without much evidence of enlargement. These points are much in favour of the view that the plague virus exerts a special action on the general lymphatic system.

In plague the lymphatic apparatus is one of the first systems to be affected. Such a preference for certain body tissues is known in bacteriology. The pathological changes produced by the plague virus in lymphatic tissue are, in my opinion, merely one of degree. There is glandular enlargement in pure septicæmic cases of the disease but no particular gland or series of glands is affected. In pneumonic cases a similar condition of affairs is found. Buboes may be found to complicate pneumonic plague and *vice versa*.

Bubonic plague, in the absence of primary pneumonic plague, forms the majority of the cases met with during most epidemics. The series of changes which occur after infection would appear to be the following. The bacillus pestis multiplies in the general blood stream and primarily exerts its deleterious action on the lymphatic apparatus. In this swelling, œdema, and hæmorrhagic extravasation take place. These changes are accompanied by a periglandular œdema and hæmorrhage which become diffuse. The degenerative action of the virus on the peripheral circulatory apparatus is now well recognised.

Summing up from a pathological standpoint the various lesions met with in a typical case of plague, one is rather drawn away from the idea that buboes are the result of infection through the skin and mucous membranes in the immediate neighbourhood. It would appear, on the other hand, that the formation of buboes in the body is dependent on the micro-organism itself, its virulence, and the individual disposition of the person or persons attacked. Simple and widespread hæmorrhagic extravasations are quite as common as buboes. They are regular hotbeds of plague bacilli and in this respect resemble the condition of affairs found in recent buboes. They also occur in fairly definite localities in the body, yet no one has thought them worthy of consideration from the point of view of the focus of entry of the bacillus pestis into the body.

Many septicæmic diseases met with in animals are analogous to plague in man. From a clinical point of view the appearances presented by such animals have so resembled plague that Orientals are firmly convinced that epidemics of a similar disease to plague break out amongst their animals some time previously to the occurrence of plague in man. The condition of septicæmia hæmorrhagica found in cattle in Hong-Kong resembles plague pathologically. In both diseases do we find general hyperæmia, general lymphatic enlargement, the occurrence of irregular areas of hæmorrhagic extravasation, œdematous infiltrations, and the presence of a micro-organism in the blood and tissues of the body. My results are more or less in accordance with those of Bitter who regards plague as a hæmorrhagic septicæmia. According to Albrecht and Ghon this is only so in severe cases.

It is said that the occurrence of buboes in definite situations in the body is strong evidence in favour of the infection having been occasioned through some focus in the area of tissue drained by the lymphatic glands which are the seat of the bubonic enlargement. Viewing the subject from certain points of view—e.g., the study of the anatomical connexions, the question of bare feet, the results of direct inoculation in man and animals, &c., there would appear to be much evidence in favour of such an occurrence.

What one has to consider is the following: Does the plague virus reach man, in nature, through the skin? Is this the natural mode of transmission of the disease from man to man? What avenues of natural infection do we find in animals? Are the modes of infection the same in man and animals? Is there clear evidence of the channels of infection in man? The consideration of these points in the presence of a large amount of plague material has led me to conclude that the opinions arrived at by many investigators are, on better acquaintance, by no means obvious. In the first place, many cases of plague are not definitely bubonic. The lymphatic glands are enlarged but no definite bubonic formation is produced. Again, in different epidemics of plague different types of the disease may be most prevalent. In one epidemic the bubonic variety of the disease may be largely in evidence; in another epidemic the septicæmic type may be responsible for the majority of the cases. Further, a certain variation during an epidemic is often found. Septicæmic plague may be most in evidence during the earlier stages of the outbreak and followed by a great increase in the number of bubonic cases during the latter half of the epidemic, and *vice versa*. Further, buboes may be double or multiple. One may be present in each groin or

in each axilla, or one in the iliac region with another in the neck. In other cases buboes are found in the most unexpected places. Again, it is asserted that femoral buboes are most common amongst those who go about barefooted.

In cases of bubonic plague it is only in rare instances that evidence is forthcoming as to the presence of wounds, abrasions, &c. It is not denied for a moment that plague infection frequently occurs through the skin and is followed by the formation of a bubo. In these cases I am of the opinion that some evidence of such an infection is usually present in the skin. In animals inoculated by this method such evidence is usually present and in all cases of authenticated infection through the skin which I have come across there has been evidence of entry of the bacillus pestis. A papule, a blister, a pustule, or even a wound is found in the skin, and frequently the bacillus pestis has been found locally. An excellent example of such a mode of infection is the following. A Chinese butcher was engaged to assist in performing the post-mortem examinations on experimental animals which had succumbed to plague. On one occasion a post-mortem examination was being held on a pig which had died from severe septicæmic plague. The butcher accidentally scratched the back of his right hand with the broken end of one of the ribs. The injury was slight and just tinged with blood. It was washed, sucked, and disinfected. It caused him no inconvenience at the time. He discontinued the necropsy at once. Two days later the man complained of sickness and diarrhoea, with severe headache and a general feeling of malaise. He ascribed the symptoms to malaria from which he frequently suffered. On the following day he felt hot and uncomfortable. The scratch on the back of his right hand felt sore and burning. His right arm felt weak with shooting pains in the muscles. The scratch showed nothing in particular. Very slight induration was made out but this was ascribed to the effect of strong antiseptic solutions. Being suspicious of plague the man was at once isolated. Slight traces of lymphangitis were found extending up the forearm. On the following morning a small vesicle had developed over the site of the original scratch. The surrounding skin was red, congested, and indurated. The lesion was extremely painful. The lymphangitis was more marked and had extended to the arm. The axilla was tender but no bubo had developed. The temperature was 102° F., the eyes were congested, the tongue was coated, and he still complained of slight diarrhoea. The contents of the vesicle were examined bacteriologically and numerous plague bacilli were found. The blood was also examined with a positive result. The man was treated in the plague hospital. A bubo developed in the right axilla. The original vesicle dried up and the lymphangitis disappeared. A few days after his admission to hospital several small vesicles developed on his legs. All contained plague bacilli. Within five days of the onset of the illness the man presented all the symptoms and physical signs of plague in its bubonic form and died seven days after admission to hospital from cardiac failure.

Such a case is interesting from several points of view—namely: (1) the exact localisation of the point of infection; (2) the pathological lesions at the point of infection; (3) the occurrence of lymphangitis; (4) the presence of the bacillus pestis in the vesicle; (5) the presence of the bacillus pestis in the blood; (6) the late appearance of the bubo; and (7) the occurrence of secondary vesicles containing the plague bacillus.

This case is a good instance of bubonic plague with undoubted blood infection. The formation of the bubo was a secondary process if we consider the exact date of the onset of the illness. The bubo did not develop for several days, during which there were headache, vomiting, diarrhoea, general malaise, somnolence, and the presence of the bacillus pestis in the primary vesicle and in the blood. Other instances of similar cases have been met with from time to time in Hong-Kong.

Again, cases of bubonic plague are known to follow the bite of a plague rat. (Cases already reported by Maxwell in his report on Plague in South China; by Clark in the Hong-Kong Sanitary Reports for 190 and 1901; by Simpson in his report on Plague in Hong-Kong; and in India by the Indian Plague Commission.) Even the bites of plague struck human beings have produced plague infection (Austrian Plague Commission). In artificially infected animals bubonic swellings are found. For instance, after setting animals with plague-infected material buboes may

be found in the groins. Cervical, submaxillary, and parotid buboes may be discovered, yet no injury of the buccal mucous membrane or carious teeth could be held accountable.

The tonsils are held by many investigators to be a channel through which the bacillus pestis effects an entry. Great stress was laid upon this avenue of infection by the members of the Austrian Plague Commission. I have frequently examined the root of the tongue and the tonsils in cases of plague and have found marked œdema, enlargement of the papillæ, and great hyperæmia of the lymphadenoid tissue and tonsils with extravasation of blood. The tonsils may be found twice or three times their normal size. The bacillus pestis has been found abundant in these situations. No evidence of such a mode of infection could be traced in experimental plague.

A careful dissection of bubonic swellings shows us that they are much more extensive than is apparent from the appearance which they present clinically. For instance, the bubo met with within the confines of Scarpa's triangle does not in a great many cases represent the focus of most intense pathological change. The bubo in Scarpa's triangle may be quite small but on cutting down on Pupart's ligament we find frequently a continuance of the hæmorrhagic extravasation around the inguinal glands. These are often somewhat larger than the femoral and the pathological changes are more marked. Further dissection centralwards leads us to the external iliac glands, in and around which one may find most intense lesions. The glands are larger, the œdema is widespread, necrosis may be present, and the surrounding extravasation of blood spreads in all directions—namely, over the ilio psoas muscle reaching the crest of the ilium, inwards to the true pelvis, and invading the broad ligament and its contents. Upwards the extravasation spreads along the iliac vessels to the aorta, spreading out like a fan over the muscles of the posterior wall of the abdomen and reaching the perirenal connective tissue and organs about the diaphragm. This hæmorrhage frequently joins another mass of blood which surrounds the cœliac glands. The latter are often enlarged, œdematous, and show extravasations of blood. These glands with the surrounding hæmorrhage form a more or less typical bubo. The condition of these cœliac glands is frequently overlooked in making post-mortem examinations on plague cases. The presence of such lesions is of importance in regard to the possibility of a gastrointestinal avenue of infection in plague.

In the majority of articles dealing with the bubonic variety of plague it is stated that there is an absence of anything like a peripheral lymphangitis. The belief is widely diffused that the infection takes place in these cases through the skin, but the bacillus pestis in its passage from the focus of its entry to the seat of bubonic formation does not excite inflammation. Beyond the possible discovery of the point of entry of the bacillus, therefore, there is no external evidence of the occurrence of such an infection through the skin. Albrecht and Ghon and many others have laid down that the absence of lymphangitis is characteristic of plague. Obvious reasons for such a statement do not, in my mind, appear to be justified. Cases observed by myself in which a definite point of entry of the bacillus pestis could be found are not confirmative of such a view. An instance of the presence of definite lymphangitis following direct cutaneous inoculation has already been given in the foregoing. Other cases have been met with and the lymphangitis present may be slight in degree but if looked for carefully it will not be missed. The persistent absence of anything like an acute lymphangitis in cases of bubonic plague is strong evidence against the skin-inoculation theory of plague. Skin infection in plague occurs only after some definite breach of continuity of the skin has taken place. Ragged nails, abrasions, minute wounds, &c., are liable in plague-infected areas to be infected with the bacillus pestis. In the absence of more definite evidence, however, the question of cutaneous infection in plague would appear to be exaggerated.

In conclusion, all bubonic swellings show the presence of extraneous micro-organisms. The infection with other bacteria would appear to occur early. The micro-organisms most frequently found present are staphylococci, streptococci, the bacillus coli, and its varieties. These organisms exert a deleterious action on the bacillus pestis and in advanced buboes are found present even in greater numbers than the bacillus pestis. It would appear to be of importance to determine what part the bacillus pestis actually takes in the formation of the bubo. In my opinion, it is

extremely doubtful if the plague bacillus can be held responsible for the full development of the bubo. In fact, my own experience leads me to believe that buboes are the result of the local growth of the bacillus *pestis plus pyogenicus* bacteria, and the latter by their more active growth cause a full development of the bubo with all its typical pathological appearances and eventually crowd out the actual bacillus *pestis* itself.

Hong-Kong.

TWO CASES OF EPIDERMOLYSIS BULLOSA.

BY AGNES F. SAVILL, M.A. ST. AND., M.D. GLASG.,
M.R.C.P. IREL,

ASSISTANT PHYSICIAN TO ST. JOHN'S HOSPITAL FOR SKIN
DISEASES, LONDON.

EPIDERMOLYSIS bullosa is still so rarely seen that the record of the two following cases occurring in the same family is of interest, especially from a histological and therapeutical point of view.

CASE 1.—The patient, a single woman, aged 26 years, was sent to me for opinion on August 2nd, 1905. She had suffered all her life from the formation of bullæ, occurring chiefly on those parts of the body exposed to friction or traumatism. She was the youngest member of a family of eight children. Both her parents were healthy and only in the case of a brother (the subject of Case 2) was there a history of any similar skin disease. There was no history of syphilis either as regarded the patient or her family but "consumption" had been present in the family of the father. The condition of the skin was as follows. On the anterior fold of the right axilla was a bulla as large as a shilling; it was tense and slightly cloudy. Over an irregular area of almost three inches long the anterior axillary fold was reddened and in parts was covered by the drying skin of former bullæ. A similar condition, but less marked, existed on the left anterior axillary fold. Two bullæ, each of the size of a sixpenny-piece, were seen on the right arm near the extensor surface of the elbow and one on the inner aspect of the calf. All were over a day old and two had a slight halo of surrounding redness. Fine white scars, remnants of frequently recurring or long standing bullæ in former years, existed on various parts of the body either alone, as on the face, or accompanied by brownish pigmentation or redness, as on the legs and axillary folds. The most serious changes existed on the shins. The lower third of both legs was practically covered with brown pigmentation and fine scarring. No varicose veins were present. Over the right shin the pigmented and cicatricial tissue extended over an area five and three-quarter inches long and four inches broad. Small pigment patches were present on the back and at the waist level where bullæ had previously occurred.

Previous history of the bullæ.—The skin at birth was healthy. When the patient was three days old the mother noticed a "blister" as large as half-a-crown on one leg, and two days later smaller ones on both eyelids. Then the face and head were constantly affected until the child was six years old. The mother states that as soon as one was healing the child would fall down and knock her face or head and then they started afresh. At one time the mother kept the child's head covered constantly with a bonnet and the hands in gloves, as she observed that blisters always followed knocks and scratching. The face and head had been rarely affected since childhood. At seven years of age the legs began to be constantly affected by bullæ, and ever since that time the bullæ which occurred on the legs lasted the longest and recurred more frequently than on any other situation. The waist was, after the legs, the most often affected until four years ago, when the patient adopted a looser style of clothing. The armpits were affected when the sleeves were tight or the lining thick. The arms were rarely attacked and the hands never. The soles of the feet were not so often involved as the legs. Bullæ had occurred a few times in the mouth. Bullæ on the face or upper part of the trunk lasted a short time, about a week; bullæ on the legs might last for weeks or months. Walking or standing about caused bullæ to arise on the legs or soles. Bullæ might appear even on parts with cicatricial tissue. The bullæ had always been larger and more frequent in summer; in winter they had sometimes

been entirely absent for a week or two. Stout and all forms of alcohol aggravated the condition; the patient did not think that indigestion affected their occurrence in any way. As regarded subjective sensations there was no itching until the bullæ were drying up. The patient might be unconscious of the presence of bullæ on the upper part of the body, but she might have much pain when they occurred on the foot or on the leg when she had to walk or to stand. She had, indeed, been obliged to lie in bed for several weeks at a time to hasten the healing of bullæ on the legs. Slight pressure did not cause the formation of bullæ, but friction applied for a minute in warm or mild weather would cause a bulla to appear several hours later. No milium-like cysts were present. The nails showed the dystrophy noted in all recorded cases of this disease. All the nails of the fingers and toes were defective and had been so since the patient was three years old. They were raised, ribbed, and discoloured, thickened at the base, pale, brittle, and irregular at the free edge.

General health.—The patient had had good general health, though she complained of being readily tired. She perspired freely and readily and suffered greatly from the cold but had never had chilblains. When excited she flushed over a sharply defined patch at the angle of the jaw and side of the neck. The heart and lungs were normal. Menstruation was regular but scanty. The patient had never had scarlet fever or measles.

Treatment and subsequent clinical history.—It appeared to me that treatment must be directed to the improvement of the cutaneous circulation and toning up of the small blood-vessels. With that aim the patient was ordered to take four grains of extract of ergot thrice daily. She adhered to this treatment during the whole of the hot month of August and she very definitely stated that she felt stronger and that the bullæ were fewer in number and less in size during that month. She omitted the ergot from Sept. 5th to 12th and during that week she developed more and larger bullæ than she had experienced during all August. From Sept. 12th to 20th she resumed the ergot and reported that she had fewer bullæ and "took much longer walks than usual without any bad effect." From Sept. 20th to 27th she had no ergot and when I saw her on the latter date several bullæ had formed. A specimen from a bulla smaller than a three-penny-piece, three days old, with a slight red halo, situated high up on the right calf, was taken for microscopical examination. A photograph of the legs was taken and this showed a tense hæmorrhagic bulla near the left internal malleolus and a flabby cloudy bulla on the sole of the left foot. On Oct. 25th the patient was seen again. She had taken ergot from Sept. 27th to Oct. 15th and had therefore taken no ergot for ten days before Oct. 25th. Only one bulla, however, had arisen since; this freedom she attributed to the fact that the weather had been dry and cold. On the 28th she developed a feverish cold and cough and was confined to bed for several days. When convalescing during the first days of November she found a bulla starting on the extensor aspect of the right elbow and though she at once took double doses of ergot another bulla developed on the opposite elbow. The weather at the same time, it should be noticed, became warm and damp. When the patient was seen on Nov. 7th she still felt very weakly. The roof of the bulla on the right elbow was taken for microscopical examination. Despite this disappointing recurrence the patient very decidedly said that since she had been under the present line of treatment she had been better in every way than she had been for years. She had previously given up all hope of improvement of the bullous eruption, having been under the care of many medical men and having attended many hospitals without beneficial result. When seen on Nov. 22nd she said she had been free from bullæ until the 20th, when two small ones developed on the toes while she was out walking. From November, 1905, to March, 1906, she continued the use of vascular tonics; as prolonged exhibition of ergot produced headaches she was only able to take ergot for a week or a fortnight at a time and during the intervals (of similar length) she took nux vomica. During the warmer weeks of May and June 1906, she had several bullæ, some being of considerable size. The nails continued to make progress in appearance. She reported herself as being improved in general health and freer from bullæ than she had been for years.

CASE 2.—The patient (a brother to the patient in Case 1), a married man, aged 44 years, had suffered from the formation of bullæ all his life. He was first seen on Oct. 25th,

1905. He had at that time two fresh bullæ, a small one which had started on the previous day just below the right thumb nail, and one on the reddened part of the right shin, two days old, and measuring nearly one and a half inches in diameter. The bulla on the thumb was tense and without surrounding redness. On the dorsum of four fingers were red patches with the dry scaly coverings of former bullæ. Over an area extending from the ankle to two-thirds up both legs and laterally in irregular patches towards the calf the cutaneous surface was reddened, in parts scaling, and in parts moist, with a drying sero-sanguineous exudation; in parts also there were pigmentation and scarring. The veins were not varicose. A section of the bulla on the thumb was taken and the roof of the bulla on the shin was also removed for microscopical examination. No milium-like cysts were present.

Previous history of bullæ.—The bullæ first appeared when the patient was one month old. He had had scarlet fever at the age of five years and measles when he was eight years of age. Bullæ appeared during both these illnesses and were much worse immediately succeeding them. The bullæ were most troublesome and frequent at the age of 16 years. At the time of examination the legs suffered more than any other part of the body. For many years past the legs had never been free from bullæ except for a few weeks during the cold weather of winter. The backs of the hands were the next most affected; then the ears. If the patient knocked the back of the nails when at work "a blood blister formed and the nail came off." The palms of the hands had never been affected; the soles of the feet were affected from the thirteenth to the eighteenth year of age. At times bullæ appeared where the collar rubbed the neck and where the sleeves pressed against the axillæ. The bullæ were always worst in warm weather. The patient did not think that they were affected in any way by drinking alcohol. He thought, however, that they were affected by the general health; at any rate, when he felt well they were less frequent. Bullæ arising on the upper part of the body or hands gave no subjective sensations till they were drying up; but when they occurred on the legs they were preceded by intense itching which subsided as the bullæ formed. The nails were dark coloured, ribbed and thickened, some having terraced free edges. Until the fourth year of age the nails had been normal.

General health.—The general health of the patient was below the average—that is to say, he had no definite organic disease but was easily tired and found standing long at his work to be "a burden." He used to feel the cold intensely, but had only rarely suffered from chilblains. The two children of the patient had no form of skin disease.

The patient was seen for the second time on Nov. 22nd after he had been taking ergot regularly for a month, and he spontaneously remarked that the bullæ were drying up on the legs "just three times as quick as usual." On Dec. 6th he remarked that the "few blisters" which had troubled him had disappeared more rapidly than they had ever previously done. On Jan. 17th, 1906, he stated that he had had better health than for many years past and that the bullæ had been fewer and had passed off very quickly. At the end of February he repeated his former statements and drew attention to the fact that his nails had grown flatter, less ridged and raised from the finger pulp, and that they were "easier to cut." During May he omitted ergot and took strychnine for a month, with the result that bullæ appeared more frequently on the leg, and the general health, in his opinion, deteriorated.

HISTOLOGICAL REPORT. (Four Bullæ were Examined)

Specimen 1 (from Case 1).—On Sept. 27th the small bulla on the calf was frozen with ethyl chloride. A section was placed in alcohol, cut in celloidin and stained with hematoxylin and eosin. The following appearances were made out on examination with the half inch and the $\frac{1}{4}$ inch oil immersion lens (Leitz). The roof of the bulla was composed of the stratum corneum and the stratum lucidum. The contents of the bulla consisted of shreds of fibrin and a number of leucocytes, chiefly the polymorphous variety, but mononuclear cells were also seen. No micro-organisms were visible. At the margin of the bulla the cells of the stratum granulosum were very swollen and hence were prominently visible even under the low power lens. Beyond the margin of the bulla the epidermis appeared to be normal; there was no degeneration of the cells of the stratum papillare as observed by G. T. Elliot (*vide infra*). At the base of the bulla the stratum granulosum cells were faintly stained, the granulation being invisible with a low power lens. In the stratum mucosum the cells of the upper layer were swollen and flattened longitudinally, the protoplasm faintly stained, the nuclei in some were granular, and in some did not take on any stain. Most of the cells showed a degree of perinuclear oedema. In the deeper layers the degenerative changes were not so marked. The lymphatic spaces between the cells were dilated and an occasional mononuclear leucocyte was seen in several of the sections. In the stratum

papillare the papillary processes were somewhat flattened, not extending so far as normal into the corium. The cells in some parts appeared slightly swollen but they stained well and showed no degeneration. The spaces between the cells were slightly dilated. In some parts there was some exudation between the stratum mucosum and the stratum papillare, with delicate threads of fibrin and a few leucocytes (see illustration). In other parts there was a slight exudation,

Specimen 1. Bulla three days old. Magnification about 37.

without fibrin, between the stratum papillare and the corium. In the corium the blood-vessels were dilated and their endothelial lining cells were swollen, but there was no surrounding infiltration. The connective tissue cells were swollen and the lymphatic spaces considerably dilated. Several sections were stained with acid orcein in order to examine the elastic tissue. A slight degree of atrophy of this tissue was found.

Specimen 2 (from Case 1).—The roof of a large newly ruptured bulla over a week old, removed from the elbow on Nov. 7th, was found to consist of the stratum corneum, stratum lucidum, stratum granulosum, and in some situations part of the stratum mucosum also remained adherent. The cells of the last were pale, scarcely taking on any stain at all, their nuclei being unstained. Adhering to the roof of the bulla were some delicate fibrin network, a few leucocytes, and granules arising probably from degenerated cells.

Specimen 3 (from Case 2).—A section of a small one-day-old bulla taken from near the thumb nail. Unfortunately it was not deep enough to include the corium. The changes were very similar to those in Specimen 1. The roof of the bulla consisted of the stratum corneum and stratum lucidum, and here and there a cell from the stratum granulosum. The contents of the bulla were a delicate network of fibrin, leucocytes, and a few degenerate cells of the stratum granulosum. No micro-organisms were seen. At the margin of the bulla the stratum granulosum was very swollen and prominently visible even under the lowest power lens and apparently disappeared at the base of the bulla where its cells and those also of the upper layers of the stratum mucosum were swollen and faintly stained. They were not, however, so degenerate or oedematous as in Specimen 1. Between two papillary processes was seen a small collection of fibrin with one or two leucocytes; at that site alone the deepest layer of cells of the stratum papillare was more faintly stained than normal. Between the cells the lymphatic spaces were somewhat dilated but no leucocytes were seen.

Specimen 4 (from Case 2).—The roof of the large bulla occurring on the unhealthy surface of the leg in Case 2 was examined and was found to consist of the entire epidermis except the stratum papillare. The stratum corneum and stratum granulosum were very thin; the cells of the stratum mucosum were flattened and swollen. The contents of the bulla consisted of fibrin and leucocytes, the polymorphous leucocytes predominating more than in Specimens 1 and 3.

Summary.—The exudation leading to the formation of a bulla occurred in Specimen 1 between the stratum lucidum and the stratum granulosum; slight exudations also occurred between the stratum mucosum and the stratum papillare, and beneath the latter; in Specimen 2 the bulla formed between the stratum granulosum and the stratum mucosum; in Specimen 3 between the stratum lucidum and the stratum granulosum; and in Specimen 4 between the stratum mucosum and the stratum papillare. No streptococci or staphylococci were found in any of the bullæ. In Specimen 1 the cutis was examined and showed no inflammatory infiltration but hyperæmia and much serous exudation. The elastic tissue showed a slight degree of atrophy.

Previous records of microscopic appearances.—The appearances described by former observers in regard to the position of the exudation do not tally, as is only to be expected with a disease the clinical appearances of which vary from bullæ without any red halo, healing in a week, to bullæ occurring on surfaces that remain permanently red from their repeated recurrence, individual bullæ healing only after weeks or months, and leaving permanent scars or pigmentation. On looking through the bibliography with the comparatively few records of microscopical examinations we find the following:—

Goldschneider (1882) found that the roof of the bullæ in his case had some prickle cells.

Bonajuti (1890) found that the bulla occurred under the

horny layer, the stratum mucosum and stratum papillare being unaffected.

G. T. Elliot (1895) found in a fresh bulla that the roof was composed of the horny layer and a large portion of the stratum epitheliale. The papillae at the base of the bulla were oedematous; the blood-vessels were dilated but not surrounded by cellular elements. In the subpapillary plexus there was extensive perivascular infiltration and the upper half of the corium was drenched with exudation. He concluded that the process was a dermatitis. In 1900, however, he had another case under his care and the examination of the bullae led him to revoke his former pronouncement that the condition was a dermatitis. The bullae examined occurred between the rete and the corium. Sections were taken from the skin of various parts of the body where no bullae were present in order to ascertain whether the entire epidermal covering was abnormal in subjects of epidermolysis bullosa. After staining with the polychrome-glycerin-ether method he found that the cells of the deepest layers, especially the layer next the corium in the interpapillary processes, showed various degrees of degeneration. He concludes that owing to the cellular degeneration present the normal coherence between rete and corium is diminished to such an extent that the former is easily lifted or swept off by the wave of serous exudation pouring out from the blood vessels in response to some irritation greater than they are subjected to under ordinary conditions. His final sentences may be quoted in full. "I still believe that the prime feature in the existence of the process is an acquired or hereditarily exaggerated irritability of the cutaneous vascular system. Whether in addition there may be a congenital instability of the cells constituting the stratum basale so that they readily and easily undergo degeneration is a question I do not feel prepared to take up at present."

Columbini (1900) found that the covering of the bulla was formed by the stratum corneum, the base by the rete cells; the papillae showed oedema and some infiltration with dilatation of the blood-vessels. The elastic tissue was normal.

Wende (1902) found the exudation occurred between the rete and the papillary layer.

Bukovsky (1903) examined a blister caused by scratching the forearm. Half an hour after the trauma it was excised and sections showed that the bulla had formed between the corium and the epidermis. There was no inflammatory infiltration round the blood-vessels. The epidermis was healthy. The milium-like bodies frequently found in cases of epidermolysis bullosa are, he points out, also found in cases of pemphigus and dermatitis herpetiformis; they are, he considers, retention cysts of the sweat-ducts due to their orifices becoming blocked in the healing of the bullae.

Concluding remarks.—From the above it is evident that the exudation in epidermolysis bullosa varies in position not only in different subjects but in different parts of the body of the same subject. The position of the exudation is therefore not an essential point in the diagnosis, as it is in the case of some bullous conditions. Much depends upon the amount of congestion and the degree of trauma. When a bulla occurs on the shins, where trauma is a frequent exciting cause, and delayed circulation an almost constant predisposing cause, and especially when the skin is already reddened and altered by previous bullae, it is clear that the entire epidermis may be readily lifted up from the corium. This was found to be the case in Specimen 3. So also when there is sufficient exudation to cause a large bulla it is natural that the abundant exudation should find an outlet deeper in the epidermis than a smaller exudation. At one time Hallopeau sharply differentiated the cases of the disease in which scars existed from those which presented no scars; since 1898, however, he has recognised them as belonging to one and the same disease. It is readily understood that where bullae repeatedly occur on the same sites, or take long to heal, some reactionary inflammation must set in and in time lead to pigmentation and scarring.

The cause of the disease is important from the point of view of prognosis and treatment. The fact that the bullae are worse in warm weather points to the dilatation of the cutaneous blood-vessels being a prominent causal factor. Treatment directed to constricting the vessels and raising the vascular tone produced in the above cases a marked improvement in a very short time. It has been noticed before that dermatitis herpetiformis has been improved by cardio-vascular tonics, and it is probable that the beneficial effect in the present cases is traceable to a similar result. In the present state of our knowledge it would not be

profitable to stray further into the realms of hypothesis or theory regarding the nervous control of the vessels. G. T. Elliot's careful and thorough examination of the unaffected skin in one of his cases proved the existence of a defective stratum basale, but the absence of such a condition in the above cases, and in most recorded microscopical observations, negatives the idea that it can account for all cases of epidermolysis bullosa. The elastic tissue in the above cases was slightly deficient; it may be that in future more attention should be turned towards this structure, its deficiency being another possible contributory cause of epidermolysis bullosa.

Bibliography.—(Dr. Wallace Beatty in the British Dermatological Journal of 1897 describes three cases of his own and gives a valuable epitome of the literature of the subject, summarising briefly all the cases recorded before 1897.) Upper Berkeley-street, W.

A CASE OF FRACTURE OF THE UPPER END OF THE TIBIA FROM INDIRECT VIOLENCE.

By R. LAWFORD KNAGGS, M.C. CANTAB.,
SURGEON TO THE LEEDS GENERAL INFIRMARY.

FRACTURES of the head of the tibia from indirect violence are met with as the result of falls upon the feet when the condyles of the femur are brought in violent contact with the articular surface of the tibia. Sometimes the internal portion of the latter may be crushed and the external lateral ligament ruptured and genu varum be produced. Also one or other tuberosity may be separated as a result of lateral flexion of the leg, as in cases of difficult labour or version. But the cases are rare and a clear history is difficult to obtain.

In the following case the patient was able to give a very definite statement of the manner and circumstances of the accident and the x rays enabled the exact nature of the injury to be established. The unusual character of the causal violence is also worthy of note.

The patient, a man, aged 45 years, was standing on a dray unloading chicory. When the accident occurred he was in the act of turning from his work and was bearing his weight upon his left leg. The right leg was slightly flexed and turned at right angles to the left. It was balanced on the fore part of the foot which was turned slightly outwards. At this moment a ten-stones bag of chicory, falling from a height of about 40 feet, struck him on the back of the head. He happened to be facing a wall and the impact knocked him against it in a leaning position, but not before he was able to raise his hands to protect himself from being dashed against it. His head was bent down upon his sternum. He was not knocked down. As soon as he tried to walk he felt pain below the right knee. When admitted to the Leeds General Infirmary there were some swelling about the right knee and much tenderness in the neighbourhood of the inner tuberosity but no deformity. Crepitus was felt but the exact situation of the fracture was not made out until some days later when a skiagram disclosed it. The accompanying diagram is a copy of the skiagram. The position of parts in it is reversed. It appears

to represent the left knee but in reality it was taken from the right. The inner tuberosity is seen to be split off from the head of the tibia obliquely, carrying with it not only the internal articular facet but also the spine. In the fibula the styloid process has been separated. There is no displacement of the parts. The treatment consisted in the

Diagrammatic representation of fracture of the upper end of the tibia from indirect violence.

application of a back splint with a foot-piece and passive movement was commenced at the end of a week. Ten weeks later the patient had a freely moveable joint and an apparently sound limb and was walking about with the protection of an elastic bandage.

There is a striking resemblance between this fracture and a Pott's fracture. Both are the result of indirect violence. In this case the fracture of the tibia was a primary lesion and the tearing away of the styloid process of the fibula followed when the compression or tendency to displacement of the parts on the inner side of the joint put the external lateral ligament on the stretch. Either the ligament or the bone might have broken; it was simply a question of relative strength. There is a strong suggestion in the skiagram of the influence which the crucial ligaments exerted in determining the exact line of fracture through the tibia, for the separated fragment carried with it the spine and in all likelihood the tibial attachments of one or both crucials. It was probably the strength of these ligaments that led to a fracture instead of a dislocation. Finally, if the description of the position of the right leg at the moment of the accident has been accurately described both the crucial and both lateral ligaments were relaxed and consequently the joint was ill prepared to receive the unexpected strain which evidently acted through the internal condyle of the femur and towards the inner side of the joint.

Leeds.

A SIMPLE FORM OF CLINICAL VISCOSIMETER.

BY A. DU PRÉ DENNING, M.Sc. BIRM., B.Sc. LOND.,
Ph.D. HEIDELB.,

AND

JOHN H. WATSON, M.B., B.S. LOND., F.R.C.S. ENG.

WHEN considering the question of a viscosimeter suitable for clinical purposes we were especially desirous of adopting a form of instrument which should be simple in construction, easy to manipulate, and at the same time require but a small quantity of blood for each estimation. The particular form which we ultimately adopted (Fig. 1) consists simply of a U-shaped piece of capillary tubing with the one arm about six centimetres in length and blown out at its upper end into a cup-shaped receiver with a thin edge (*o*), whilst on the short arm, about two centimetres in length, there is a small elliptical bulb. As the most convenient place from which to take the blood necessary for an estimation we have

preferred the lobe of the ear, for not only is it less sensitive than any other part but it can be made to bleed readily without any manipulation, whilst the position of the hanging drop permits the viscosimeter to be always placed vertically underneath.

FIG. 1.

Clinical viscosimeter.

The method of making an observation of the viscosity with this instrument is as follows. The lobe of the ear is first well cleaned with ether and a special fine-pointed knife is then inserted into the most dependent part of the lobe. The viscosimeter, which has previously been warmed to the temperature of the patient's body, in much the same way as a clinical thermometer, is placed beneath the hanging drop of blood (Fig. 2) and the receptacle of the instrument is filled. The moving thread of blood is carefully watched through its course down the longer limb and round the bend of the tube; the seconds finger of a stop-watch, which has been held in readiness, is started as soon as the column of blood reaches the point *M'* and is stopped the moment that it gains *M''*. The time which will now be read off to one-fifth of a second is that taken by a quantity of blood sufficient to fill the elliptically shaped bulb in flowing through the long

FIG. 2.

Showing method of employment of the viscosimeter.

capillary arm of the instrument. This time value when compared with that given for water, for which the viscosity is well known, gives us directly the viscosity coefficient of the blood.

When using these tubes the following points must be observed, otherwise serious discrepancies and irregularities may arise.

1. The tubes should be scrupulously clean. After use they

are best cleaned as follows: The blood is at once driven out by a small force pump in order to prevent clotting occurring in the tube. The viscosimeter is then filled with nitric acid and placed aside for a short time; the acid is then replaced by distilled water, alcohol, and ether and the tube is finally dried by blowing a current of air through it.

2. The viscosimeter should be previously brought to the temperature of the patient. The temperature should be noted.

3. The receptacle of the instrument must be filled with blood, for if the column in the capillary breaks from the fact that there is an insufficiency of blood the estimation is valueless on account of the uncertainty in the pressure head which the method presupposes a constant.

4. It is a wise precaution to affix on to the short arm of the tube a small piece of rubber tubing, so that if the blood should at first refuse to flow through the instrument movement may be initiated by slight suction.

5. Viscosity determinations should as far as possible always be accompanied by simultaneous blood counts.

Mr. T. Hawksley, of 357, Oxford-street, London, W., has undertaken to prepare cases containing half a dozen of these viscosimeter tubes, a stop-watch, a small force-pump, a special needle, and a short length of rubber tubing. He will also separately supply fresh viscosimeter tubes in half dozens.

This instrument, which we have now been using for the past four months, has been found to give very satisfactory results. In our observation on healthy people we have obtained values ranging between 4·8 and 5·6 times that of water at blood temperature; whereas in pathological states we have recorded considerable variations.

NOTES UPON FIVE CASES OF RENAL NEOPLASM.

BY DAVID WALLACE, O.M.G., F.R.C.S. EDIN.,
ASSISTANT SURGEON TO THE ROYAL INFIRMARY, EDINBURGH.

DURING the last decade renal surgery has made marked progress, chiefly because of the greater safety with which operative procedures can now be carried out compared with formerly and also, particularly more recently, because of the advances which have been made in the investigation of the condition of the renal organs, not merely in their combined functioning, but also in regard to their individual capacity. I do not propose to describe the methods now commonly in vogue to assist diagnosis and prognosis in renal surgery but those upon which chief reliance may be placed are:—

1. *For both kidneys:* (a) The examination of the urine as regards the daily quantity, the specific gravity, and presence or absence of abnormal products; (b) the estimation of the urea excreted in 24 hours; (c) the freezing point of the blood (cryoscopy); and (d) the fluoridzin and methylene-blue tests.

2. *For each kidney:* (a) Cystoscopic examination of the bladder, noting the appearance of the ureteral openings and what comes from them—e.g., blood or pus; (b) ureteral catheterisation, with the use of the above tests to the urine collected from each kidney; and (c) Luys separator, with or without indigo-carmin subcutaneous injection.

The history given by, and the examination of, a patient may materially assist in the diagnosis of a renal neoplasm, but it must be recognised that the history may be most misleading and that frequently hæmaturia and other symptoms common to several diseases and to different parts of the urinary tract may be thought to be vesical in origin when due to kidney affections, or *vice versa*. Even if one kidney be enlarged and palpable the difficulty is not wholly overcome, as the enlargement may be compensatory to disease of the other kidney or there may be bilateral disease (Kummel). Or again, a patient may have an enlarged kidney, but the prostate may also be enlarged and the bleeding may have the characters associated with bladder trouble. To determine, therefore, from which part of the urinary tract hæmorrhage arises may be difficult. There are certain signs which are presumptive evidence of renal neoplasm, but in the majority of cases, if not in all, it is probably a wise precautionary measure to examine the bladder cystoscopically to exclude vesical affections and at the same time,

if possible, to get definite evidence of a kidney affection by observing the urine as it passes from the ureter. In some of the cases where bleeding is present this is not difficult and it materially assisted the diagnosis in the first patient whose history is quoted below. Hæmaturia is not infrequently the first symptom in both renal and vesical neoplasm and in such cases the chief means of diagnosis is cystoscopy. Examination of the urine in many cases of hæmaturia wholly fails to give any clue either to the source or cause of the bleeding—no tumour cells or tube casts being seen, even after repeated microscopic examination of deposits from centrifuged urine. These statements are almost self-evident but they seem worthy of remark as they are frequently forgotten and error in diagnosis and treatment results.

Renal tumours may occur at any age and are observed with almost equal frequency in the two sexes and unfortunately they are not uncommonly malignant. A local tumour may be observed before any symptoms are manifested but frequently hæmaturia is the first thing observed by the patient even in cases where the kidney has attained a considerable size. The quantity of blood lost has no relation to the size of the tumour and the bleeding may be extremely profuse. The bladder may actually become over-distended with blood clot. The urine may be very dark in colour or bright red. Irregular clots may be passed as if from vesical bleeding but these and the dark colour of the blood may simply mean that free bleeding has occurred but that micturition has not immediately followed the inflow of blood to the bladder. Worm or string-like clots, casts of the ureter as seen in Case 4, are not in my experience common. Indeed, it may be said that the old dicta regarding hæmaturia are valueless and are sources of error.¹ Some of these points were illustrated in the following five cases upon which I have operated and of which I give the histories.

CASE 1.—The patient, aged 63 years, was a healthy man who had been exposed to considerable hardships in many countries. For three or four months he had observed at intervals a little blood in the urine but at no time had the bleeding been severe. No cause for the bleeding had been discovered and it was unassociated with pain or any other symptom. On examination of the abdomen the left kidney was found to be enlarged, readily palpable, and irregular on its surface. Cystoscopy showed blood coming from the left ureteral orifice while the bladder was healthy. Neoplasm of the left kidney was diagnosed and nephrectomy advised.

Nephrectomy through a lumbar incision was performed. The operation presented no difficulty as there were few adhesions. The patient made a good recovery, the wound healing by first intention. The tumour replaced practically all the kidney substance and microscopically proved to be an adenocarcinoma.

With regard to the after-history, the patient died one year and five months after the operation "apparently from senile decay." At the necropsy the seat of operation was healthy, the ligatured pedicle being represented by a small mass of fibrous tissue. There were no secondary deposits.

CASE 2.—A married woman, aged 30 years, first noticed blood in the urine in February, 1901, and from that date at intervals of two or three weeks bleeding recurred and lasted on each occasion for three or four days. The bleeding was usually worst during menstruation. In June, 1901, clots were observed for the first time and the bleeding persisted longer than on previous occasions. Some of the clots were string-like but many were large and irregular. At this date also, for the first time, she had pain in the right loin and frequency of micturition. In August, when the patient was first seen by me, she was extremely anæmic. The right kidney was easily palpable and irregular in shape. The urine contained much blood; it was red but without clots. The specific gravity was 1020. There were no tube casts or special cells. The amount of urine was 40 ounces daily. The bleeding was continuous; there were no intervals of clear urine. Neoplasm was diagnosed and nephrectomy was advised. For a week previous to the operation calcium chloride, 15 grains thrice daily, was administered.

Operation was performed on August 13th. Nephrectomy through a lumbar incision was done, the kidney being readily excised, as there were no adhesions. The patient made a good recovery, the wound healing by first intention; she was out of bed on the twelfth day and left the hospital

¹ Vide Edinburgh Hospital Reports, vol. II.

for home on the twenty-first day from the date of the operation. The tumour was localised to the upper part of the kidney and was wholly within the capsule but a mass attached by a narrow pedicle filled the pelvis of the kidney. Microscopic examination proved it to be an adeno-carcinoma of the Gravitz type—i.e., a nephroma.

As to the after-history, the patient is perfectly well four and a half years after operation.

CASE 3.—A man, aged 50 years, one year before coming under observation had blood in his urine for a week. He was unable to assign any cause for its presence. It seemed perfectly symptomless and there was no recurrence until six weeks previously (June, 1901) when again without any cause bleeding began. During these six weeks he had lost much blood and the bleeding was still very severe, solid clots forming in the vessel. He had no pain or other symptom, unless frequency of micturition. The left kidney was much enlarged and very easily palpated, irregular and elastic to touch. He had never had any discomfort from it and it was not painful on pressure. Cystoscopy showed a healthy bladder and bleeding having ceased the day the examination was made no blood was observed coming from the ureter. The diagnosis of neoplasm was made and operation was advised. A very large varicocele was observed on the left side which the patient asserted had only come on three months previously. That the varicocele had only existed during that time was almost certain as he found it so inconvenient and was so alarmed by it that he consulted a surgeon at once (*vide* remarks).

Operation was performed on August 10th, 1901—nephrectomy through a lumbar incision. The kidney was adherent to the surrounding tissue but not firmly; very free bleeding occurred while loosening it. A mass of tumour filled the renal vein and pressed on the inferior vena cava. This mass could not be removed and was ligatured along with the vessels while the ureter was separately dealt with. The patient made a good recovery. The wound healed by first intention, but a week later there was evidence of some tension and on introducing a pair of sinus forceps a quantity of serum was evacuated. A sinus persisted from which a thin sanious fluid discharged for several weeks. By Sept. 1st the patient was out of doors and able to walk about. On Oct. 1st he was back to business. The tumour replaced almost the whole of the kidney substance and microscopically was a round-celled sarcoma.

With regard to the after-history, for four months the patient was able to do his work but in February, 1902, he began to lose ground and by March was confined to his house. At this date a tumour of large size could be palpated in the left lumbar region, anteriorly, which moved freely with respiration. He died in September, 1902, 14 months after operation.

CASE 4.—A man, aged 52 years, had at intervals during the last six months observed blood in his urine. The blood was intimately mixed with the urine which was porter-like, never red in colour. Occasionally irregular clots were present. The bleeding came on without any cause but now and then he noticed pain along the line of the left ureter anteriorly. There was no pain in the posterior lumbar region. I saw the patient in December, 1903, three days after the occurrence of a much more profuse hemorrhage than there had previously been, and which was associated with great pain in the bladder and marked frequency of micturition. Catheterisation had been used but gave no relief at the time and since its first use he had failed to pass any urine naturally. The bladder was over distended and so firm that I concluded it was full of blood clot. The prostate was not enlarged and the kidneys were not palpable. I advised no operation, washed out the bladder, and pointed out that the clot would probably gradually break up and be got rid of. In the course of four days this took place and after the clots were got rid of the urine was passed naturally and free from blood. Three weeks later cystoscopic examination showed the bladder to be healthy and the ureteral openings normal in appearance. One or two worm-like blood clots were passed with the urine but no other bleeding took place. Pain having been on the left side the diagnosis of probable left renal tumour was made and nephrotomy was advised.

Operation was performed. A lumbar incision exposed the kidney which had a smooth enlargement of about the size of an orange at the upper pole under the capsule, and the organ was therefore excised. The patient made an uneventful recovery. Microscopically the tumour was an adeno-carcinoma

of the Gravitz type—i.e., a nephroma. Now, two and a half years after the operation, the patient is in excellent health and has not had a bad symptom.

CASE 5.—A woman, aged 35 years, 12 months previously (August, 1900) complained for the first time of a gnawing pain in the right side which lasted for a fortnight. Five weeks previously (July, 1901) she had pain in the right side and frequency of micturition, and observed that the urine was discoloured. This discolouration was found by her medical attendant to be due to pus, and on August 25th, 1901, there was a considerable quantity of pus in the urine. She had never passed blood. The urine had a specific gravity of 1020 and contained much pus. The quantity of urine per diem was 40 ounces. Tubercle bacilli were present in the deposit. The right kidney was easily palpable and tender on pressure. It was irregular on its surface. The left kidney was not easily detected on palpation. The diagnosis was tuberculous kidney.

Operation was performed on Sept. 3rd, 1900. Through a lumbar incision the right kidney was exposed and an abscess was detected with its wall adherent to the peritoneum. It was determined to remove the kidney as from its irregularity and size it was believed to be extensively tuberculous. During its separation from the surrounding structures the nature of the condition was recognised to be polycystic, but as there was one abscess of some size presumably tuberculous in nature and the cause of her symptoms, the excision was proceeded with. At the point where the peritoneum was adherent the peritoneal cavity was opened, but the opening was immediately plugged with gauze and later sutured with catgut. The patient made a good recovery and the wound healed by first intention. The kidney was a typical polycystic growth, cysts varying in size from many minute cavities to cysts as large as a walnut. The abscess communicated with the pelvis of the kidney.

As to the after-history, the patient left hospital on the fourteenth day after operation. The day after operation the quantity of urine secreted was 32 ounces and during her stay in hospital the quantity averaged 30 ounces. For two and a half years after the operation the patient remained quite well, had no pain or frequency of micturition, and the urine was free from pus. She also gained weight. The left kidney had become palpable, even though the patient was stouter, but it did not seem to be very irregular in outline. One year later she died with symptoms of general peritonitis but her medical attendant informed me that she had at no time any symptom of renal insufficiency.

These five cases illustrate four types of renal tumour: (1) adeno-carcinoma invading the whole of the kidney; (2) adeno-carcinoma (nephroma) (the type of tumour described by Gravitz as adrenal rest tumours); (3) sarcoma; and (4) polycystic. In each of the first three cases reported the affected kidney was readily palpable. In Case 2, indeed, the kidney was so mobile that, being the right and in a woman, it was thought at first to be an example of moveable kidney with hæmaturia; the quantity and persistence of the bleeding, however, together with the irregular shape of the swelling, made the diagnosis of neoplasm comparatively easy. The other three, although readily palpable, were not so mobile and in Case 1 and Case 3 the irregularity was strongly in favour of neoplasm. In Case 3 (the sarcoma) the irregularity and increased size were very manifest. There was no bleeding when cystoscopy was used and the bladder was seen to be quite healthy, with no abnormal appearance at the left ureteral orifice. In this case also the varicocele on the left side was very striking and the definite statement of the patient that it was of recent origin—of three months' duration—pointed to local interference with the venous return. Such a varicose condition, with a history of recent onset, is a point of importance and should always be remembered as a possible assistance in diagnosis. Mr. Henry Morris specifically mentions varicocele² as an occasional result of renal neoplasm and remarks that he drew attention to it in 1884, Guyon having previously described it in 1881. Lequeu attributed it to pressure on the spermatic vein by enlarged glands but Morris believes that it may be due to pressure on that vein directly by the tumour. In Case 3 the renal vein was blocked by tumour growth and at the removal of the kidney this projecting portion was cut through, it being impossible to remove it. Morris points out that if the varicocele in such cases was invariably due to glandular invasion and pressure,

² Surgical Diseases of the Kidney, 1901.

as Lequeu says, it would contra-indicate operation. This patient rapidly lost ground but for nearly five months after operation he was able to attend to his business and after the operation there was no recurrence of hæmorrhage. I believe his life was prolonged and rendered more comfortable by operation (than if no operation had been performed) but, on the other side, it must be remembered that the operation was one of much gravity and that a mass of tumour was knowingly left behind. In similar circumstances I am not prepared to say I would advise operation. In Case 5—the polycystic kidney—the symptoms were solely due to the accidental presence of a tuberculous abscess, a rare complication in such cases. There was none of the symptoms associated with polycystic kidney, a fact explicable on the ground that the tumour had not attained a large size. Hæmaturia, sometimes present in such cases, was absent. As the polycystic condition is usually bilateral operative interference is, as a rule, deprecated, more particularly as removal of one kidney has seemed to hasten the cystic degenerative changes in the other but operation has been successfully performed in several instances where removal seemed justified because of pain, &c.

An analysis of the symptoms in the first four cases shows: (1) that hæmaturia was the first symptom in each and that, indeed, no other symptom was complained of; (2) the bleeding in three was very profuse and had the characters of vesical hæmorrhage; (3) in Case 1 the bleeding was small in quantity although the tumour was a large one, replacing nearly the whole of the renal substance; (4) in only two (Cases 2 and 4) were worm-like clots observed and in Case 4 only months after the onset of the bleeding; and (5) in none were there any tumour cells or casts discovered in the urine.

HOSPITAL PRACTICE BRITISH AND FOREIGN.

Mulla autem est alia pro certo noscendi via, nisi quamplurimas et corborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

A CASE OF ENLARGED WANDERING SPLEEN; SPLENECTOMY.
(Under the care of Dr. R. H. LUCY.)

A WOMAN, aged 21 years, but looking a mere child, was sent to the South Devon and East Cornwall Hospital on March 24th, 1905, by Mr. J. Telfer Thomas of Oamborne for abdominal swelling and pain, with occasional vomiting. Her family history was negative but the patient stated that she had always been "delicate" and had passed through the usual illnesses of childhood. At the age of 12 years she became "jaundiced" with some, though not severe, abdominal pain. When 13 years old both legs ulcerated—purple spots followed by slight swelling, desquamation, and ulceration. An attack of influenza followed by "jaundice" and slight abdominal pain occurred when she was 19 years old. Menstruation commenced at the age of 17 years, never quite regular, merely a scanty loss for two days. Two years before admission, when recovering from her second attack of "jaundice," she noticed while dressing a hard swelling above the left groin, moveable, not tender, variable in size, "sometimes double what it was at other times," while the history she gave and persisted in was very suggestive of a left-sided intermitting hydronephrosis. For the past two years the general health had been fair with occasional attacks of vomiting and faintness, when the abdominal tumour seemed largest, but there was comparative comfort in the intervals. The patient was well nourished but had a peculiar straw-coloured tint. No blood examination was made previously to operation. The diagnosis varied between enlarged left kidney and left ovarian tumour.

On April 1st, under anaesthesia, a hard moveable mass could be felt in the left lumbar, umbilical, and hypogastric regions. Per vaginam the lower pole lay anterior to the uterus and apparently was moulded to the pelvis. The

abdomen was opened in the middle line from the navel to the pubes and the hugely enlarged dark purple spleen was gently and carefully lifted out on to the parietes. It was seen that owing to rotation of the organ on its vertical axis the characteristic notches faced backwards and so made a definite diagnosis, even under anaesthesia, impossible. This rotation had also caused torsion of the pedicle and great engorgement; the pedicle was long enough to allow easy delivery on to the parietes, being about two inches broad and composed of huge thin-walled veins and tortuous pulsating arteries. The pedicle was clamped with stout compression forceps close to the hilum and transfixed and tied in two halves with stout catgut on the proximal side of the forceps and the organ was cut away, leaving a voluminous "cuff" of peritoneum beyond the ligatures; the component vessels were then tied off separately with fine catgut and the peritoneal cuff was cast over the face of the stump with similar material. On releasing the latter it glided easily upwards and backwards under cover of the left lower ribs. After ascertaining that the pedicle was clear of bowel and that the other abdominal viscera were healthy the abdomen was closed by mass sutures of silkworm gut. On removing the forceps 25 ounces of blood escaped from the splenic vessels, and when drained the organ weighed 22 ounces, or 47 ounces in all.

After operation the patient became somewhat collapsed and complained of great pain in the left hypochondrium which was eased by one-sixth of a grain of morphine given hypodermically. On the second day she complained of abdominal pain with some distension. Her temperature was 101° F. and her pulse was 112. Slight pleural friction was detected on the third day at the left base posteriorly, while the bowels acted freely on the fourth morning and the temperature steadily declined and became normal on the eighth day, rising again to 101·6° on the tenth evening and became, and remained, normal on the fifteenth day and onwards. The sutures were removed on the ninth day and the wound was found to be soundly and cleanly healed. 5 grains of red bone medulla were ordered to be given thrice daily on the fifteenth day and was continued till her discharge from the hospital on May 1st, when she looked ruddy and well, and there was no enlargement of any lymphatic glands.

On April 28th Dr. W. L. Pethybridge, honorary pathologist to the hospital, reported that a specimen of the patient's blood yielded the following result on examination: red cells, 4,000,000 per cubic millimetre (80 per cent.); hæmoglobin, 70 per cent.; and white cells, 10,000 per cubic millimetre. A differential count of the white cells showed: polymorphonuclears, 68 per cent.; small lymphocytes, 23 per cent.; large lymphocytes, 5 per cent.; and eosinophiles, 4 per cent. No abnormal cells, either red or white, were seen. On May 6th Dr. Pethybridge reported that a microscopic section of the spleen showed no deviation from the normal structure. Dr. Lucy recently heard from Mr. Telfer Thomas that the girl looks and expresses herself as being perfectly well and free from pain.

Remarks by Dr. LUCY.—Cases such as the above are of great clinical interest from the fact that a correct diagnosis is seldom possible before operation owing to the spleen, by its enlargement, losing its characteristic shape, and if in addition it rotates on its pedicle the notch or notches cannot be felt. Increase in bulk and weight causes early elongation of the pedicle and so allows excursions of the spleen into regions of the abdomen where least expected. I regret that I did not ask for a blood count before operation but I confess that the shape and position of the tumour did not suggest an enlarged wandering spleen to either my colleagues or myself for even under anaesthesia one of the former, who made a vaginal examination, thought it was an enlarged kidney, the original diagnosis being an ovarian tumour. The girl's own history—elicited without leading questions—suggested most strongly intermitting hydronephrosis.

I wish to thank my colleagues, Mr. C. E. Russel Rendle, for assistance at the operation, and Dr. Pethybridge for his pathological reports.

WESTERN INFIRMARY, GLASGOW.

A CASE OF INTUSSUSCEPTION; OPERATION; RECOVERY.

(Under the care of Dr. DUNCAN MACARTNEY.)

THE patient, a boy, aged one year and eight months, was sent to the Western Infirmary by Dr. James Todd of

Maryhill on August 18th, 1905, and was admitted under the care of Dr. Duncan Macartney who was acting for Dr. T. K. Dalziel at that time. The child was taken ill suddenly that morning and when Dr. Todd was called in he at once recognised the serious condition of the patient and hurried him into hospital seven or eight hours after the onset of the disease. The child was a poorly-nourished, thin little creature in a state of collapse. There had been vomiting, tenesmus, with blood in the stools, and a rounded swelling could be felt in the right inguinal region. When the parts had been carefully prepared for operation and the child put under an anæsthetic a median incision was made below the umbilicus. The mass was easily felt but as it did not readily come through the wound it was manipulated in the cavity and fairly easily reduced. When reduced the parts were brought out of the wound for inspection and showed that not more than two or three inches had been inflected, as could be noted by the congested state of the intussusceptum. Half of the appendix had been included in the intestinal grip which gave it an exceedingly curious appearance—one half being vividly congested, the other and terminal half being normal. The abdominal wall was sewed together by three or four salmon-gut sutures passing through the whole thickness of the abdominal wall. The recovery was uninterrupted, though the temperature, which before operation was subnormal, rose on the second day to over 102° F. The child was dismissed plump and well after five weeks' residence in the infirmary.

Remarks by Dr. MACARTNEY.—Recovery after this operation depends on the amount of injury that has been done to the intussuscepted portion of the intestine. The less injury that is inflicted on the serous covering of the bowel the less chance there is for the escape into the peritoneal cavity of intestinal fluid and the organisms therein. The more that serous covering is devitalised the more certain the cavity is to be invaded. Other similar cases which have come under my care divided themselves into two classes. The first group contained those that, after operation, remained in the condition of shock, never recovered either pulse or temperature, and simply "went on dying." They had received their lethal dose before ever they came to the operating table. The other group contained those in whom the temperature after operation immediately flies up to 104° F. or over, ending fatally after a few days. In this class there has been absorption of septic material not in such quantity as in the first group yet too much for the enfeebled life to overcome. The rapid rise of temperature is at once a proof of a large or virulent amount of poison and an effort on the part of the child to fight for the result. In short, it might be said that the success of this procedure depends almost entirely on the early recognition of the state of affairs and prompt action thereafter. On these points Dr. Todd is to be congratulated.

There is no method of treatment other than abdominal section that can be recommended. Inflation by air or water is at best a very doubtful means; it so rarely succeeds perfectly that operation has to be resorted to afterwards, and the shock which is caused by dilatation of the lower bowel, together with the time wasted in so doing, only lessens the margin of recovery on which the operator has to work.

Medical Societies.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—The provincial meeting of this society was held at the Radcliffe Infirmary, Oxford, on June 23rd.—Professor W. Osler was in the chair during the exhibition of clinical cases and pathological specimens and Dr. W. Collier when the papers were read.—Mr. A. P. Parker exhibited a boy with Dislocation of both Patellæ outwards.—Mr. H. P. Symonds exhibited a girl with a Solid Tumour of the Pelvis, probably enchondroma.—Dr. W. J. Turrell exhibited a well-marked case of Achondroplasia in a girl.—Dr. E. Mallam exhibited a child with Enlarged Liver and Spleen for diagnosis.—Dr. Mallam also exhibited three cases of Calf Ringworm and Miss Fitzgerald showed microscopic specimens and cultures from these cases.—Mr. G. Pernet exhibited Cultures of Ringworm from the Scalp and Nails.—Mr. P. H. Adams exhibited a case of Lamellar Cataract in which the patient also suffered from Ichthyosis Simplex.—Mr.

Finch exhibited a well-marked case of Cretinism in a child.—Dr. R. H. A. Whitelocke exhibited a girl with Double Hernia of the Ovary whose sister had suffered from the same trouble and from whom one ovary was removed by operation and reported on at a previous meeting of the society.—Mr. A. P. Parker exhibited a specimen of Congenital Malformation of the Intestines in a Full-time Fœtus. In this specimen the stomach was normal but the duodenum was enormously distended and at the duodeno-jejunal flexure there was complete occlusion of the tube of the gut and the rest of the intestine was lying in a corkscrew manner with a small mesentery.—Dr. George Carpenter read notes of a case of Acute Osteomyelitis of the Spine in an Infant, a girl, aged one year. She looked ill and was anæmic and somewhat wasted. In the left loin there was a large smooth, rounded, and fluctuating swelling, dull on percussion and very tender. The child died six days after admission. The left pleura contained about two pints of purulent fluid. In front and to the left of the first, second, and third lumbar vertebræ there was a quantity of pus and the cavity communicated with the left pleura. Microscopical examination of the pus showed streptococci and diplococci. No tubercle was present.—Dr. E. C. Williams read some notes of a case of Congenital Heart Murmur in an infant, aged five months, suffering from an attack of whooping-cough.—Mr. H. P. Croly read notes of a case of Intussusception in an infant, aged nine months, successfully operated upon by Dr. Whitelocke at the Radcliffe Infirmary. The operation took place eight hours after the first symptom and it was found that the intussusception was of the ileo-cæcal variety.—Dr. B. M. H. Rogers read notes of a case of Acute Atrophy of the Liver in a boy, aged four years. When first seen he was distinctly yellow and was very sick and complained of abdominal pains. He became delirious and in lucid intervals complained of headache; the jaundice was now well marked. He died two days after admission. The liver was about the usual size and there was no obstruction to the flow of bile.—Dr. A. G. Gibson read a paper entitled "Some Observations on Enlarged Veins in Children." A large proportion of children taken to the out-patient department of any hospital suffered from loss of appetite, wasting, and general debility. Physical signs were, as a rule, few. In many of them, however, veins in various situations were more easily seen than in normal children. The commonest situation was on the front of the chest but they were found frequently on the back between the shoulder blades, under the chin, and on the temples. The veins were exceedingly small and were flush with the surface of the skin. These venous ramifications were not seen in all thin children, as, for instance, in the wasting that resulted from a cerebral tumour; hence it was probable that these veins were dilated. That in some there was venous obstruction was shown by the presence of dilated external jugular veins on one or both sides even in the upright position. On deep inspiration they did not collapse as did jugular veins in other subjects—e.g., a patient breathing deeply under an anæsthetic. Accurate records had been kept of 14 such cases showing as the cardinal sign dilated jugulars on one or both sides which did not collapse on inspiration. Of these, seven were male and seven were female; the age varied from four to ten years; a history of tuberculosis in the family was obtained in eight cases; the symptoms were either lassitude or wasting, or referred to the digestive or respiratory systems, such as frequent attacks of vomiting and diarrhoea and attacks of bronchitis or some form of chest trouble. The left jugular vein was enlarged in 14 and the right in 12; veins on the chest were visible in 13 cases, on the back in two, under the chin in two, and on the temples in seven. Downy hair on the back was found in six cases. The retraction murmur was present in ten. Small glands in the neck or elsewhere were present in nine cases. Tuberculous peritonitis was present in two cases while in a third the signs suggested a similar condition. Only in one case had it been possible to observe the anatomical condition under which the dilatation of the veins was produced. This was in a case of tuberculous peritonitis in which a dilated left jugular vein had been noticed for some time previous to death. A dissection of the anterior mediastinum showed a ring of small fleshy glands surrounding the left innominate vein. Sections made from one of the glands showed a few giant cell systems and tubercle bacilli. The posterior mediastinum in this case showed several hard caseating glands with large numbers of tubercle bacilli. The cases corresponded in character to those described as being

due to tuberculosis of the mediastinal lymph glands; and without implying that dilated jugular veins which did not collapse on inspiration were pathognomonic of such condition, it was suggested that in the presence of a tuberculous history, symptoms of debility, small glands in the neck, veins on the chest, back, neck, or temples, a retraction murmur, and in the absence of signs pointing to syphilis, lymphadenoma, or lymphosarcoma, the sign may be of value in the diagnosis of early tuberculosis.

Reviews and Notices of Books.

A System of Gynaecology by Many Writers. Edited by THOMAS CLIFFORD ALLBUTT, the late W. S. PLAYFAIR, and THOMAS WATTS EDEN. Second edition. London: Macmillan and Co., Limited. 1906. Pp. 949. Price 25s. net.

DURING the ten years which have elapsed since the appearance of the first edition of this book such great strides have been made in gynaecology that it has been found necessary practically to rewrite the greater part of the present volume. More especially has this been the case in regard to the surgical portions of the work. The two articles, for instance, on ovariectomy and hysterectomy are entirely new and have been written by Professor J. W. Taylor and Professor H. R. Spencer. Additional surgical articles dealing with Antiseptic and Aseptic Technique by Dr. T. W. Eden, on Minor Operations on the Uterus by Dr. Amand Routh, on Vaginal Hysterectomy and Colpotomy by Professor Spencer, and on the After-treatment of Gynaecological Operations by Dr. G. E. Herman have been added. There are entirely new articles on the subjects of diseases of the ovaries and pelvic hæmatocele and the sections on chorion epithelioma and gonorrhoea are included for the first time. In the preparation of this new edition Professor Clifford Allbutt has enlisted the services of Dr. Eden.

The book maintains its main characteristics and presents very completely the current teaching of English gynaecologists of the more conservative type. One of the more important of the new chapters is that on Chorion Epithelioma, by Dr. J. H. Teacher and Dr. Eden. It contains a large number of excellent illustrations and embodies the important work carried out by Dr. Teacher on this subject. In the section on Pelvic Hæmatocele the notable plates first published by Professor Bumm in his "Grundriss zum Studium der Geburtshilfe" have been introduced, whilst the section on Extra-uterine Gestation by Mr. J. Bland-Sutton has been brought fully up to date. The article on Antisepsis and Asepsis in Relation to Gynaecological Surgery contains a clear account of the principles which should guide the surgeon in his choice of the various methods of attaining the desired results, while the practical details of the sterilisation of dressings and the surgeon's hands, and so on, are given in sufficient detail. Professor Taylor's article on Ovariectomy is one of the best in the book and those by Professor Spencer on the different operations of hysterectomy are most interesting. The latter is strongly in favour of the use of the electric cauterium in the performance of vaginal hysterectomy and is inclined to attribute the bad results obtained after different methods of operating for carcinoma of the cervix uteri mostly to radical differences in operative technique, and he considers the most important point of all to be the avoidance of the local implantation of cancer cells. The question of the treatment of carcinoma of the cervix uteri by the extensive abdominal operations associated with the name of Professor Wertheim is discussed and Professor Spencer comes to the conclusion that the figures given by Wertheim indicate that a more complete removal of the growth is possible by the abdomen

than by the vagina and that the increased number of cases free from recurrence after the abdominal operation is due, therefore, to freer removal of the growth.

The great importance of gonorrhoeal infection of the female pelvic organs fully warrants the introduction of a special article on this subject. It is written by Dr. J. B. Hellier and gives a very good description of the results of gonorrhoeal infection as they come under the notice of the gynaecologist. The important question as to whether we have in these cases to deal with an infection directly due to the gonococcus or to the associated action of other organisms is one about which there is still a great deal of dispute. Dr. Hellier appears to favour the view so strongly supported by Wertheim, that the gonococcus is itself capable of producing suppuration without any admixture with other pus-producing organisms. In the section on treatment, the abuse of the curette in dealing with these cases is justly condemned; as Bumm has pointed out the curette is a very poor weapon with which to make war on micro-organisms. Thus, if a recently married woman complains of dysmenorrhoea and menstrual excess we must carefully exclude the possibility of the cause being the gonococcus before proceeding to dilatation of the cervix or curettage of the body of the uterus. The great importance of allowing sufficient time for a cure to occur in cases of disease of the appendages due to the gonococcus before resorting to operative interference is insisted upon, and the dictum of Fritsch, that expectant treatment should be carried out for six months before an operation is thought of, is quoted with approval.

As we have said, the general tone of the work remains the same as in the first edition, and, as the editors point out in the preface, the friendly reader will perceive that although great progress can be recorded the lapse of ten years has left the conservative tendencies of British gynaecological practice to a large extent unchanged.

Heart Disease and Aneurysm of the Aorta, with Special Reference to Prognosis and Treatment. By Sir WILLIAM H. BROADBENT, Bart., K.C.V.O., M.D. Lond., F.R.S., D.Sc., LL.D., F.R.C.P. Lond., and JOHN F. H. BROADBENT, M.A., M.D. Oxon., F.R.C.P. Lond. Fourth edition. With 39 illustrations. London: Baillière, Tindall, and Cox. 1906. Demy 8vo, pp. xvi.-479. Price 12s. 6d. net.

THE new edition of this work is mainly from the hands of Dr. John F. H. Broadbent who has revised and rewritten the chapters on acute and malignant endocarditis and that on affections of the myocardium. Sir William Broadbent has, however, made several important additions to the chapters on angina pectoris and functional affections of the heart and has carefully revised the whole of the proofs. Thus the student of this interesting subject has the advantage of reaping the results of the labour of the younger man tempered with the more mature views of the veteran. The subject of the prognosis of heart disease has always been a favourite one with Sir William Broadbent, dating from the time when he was house physician to that great authority on the heart, Dr. Sibson of St. Mary's Hospital. The present work at its origin was for the most part a reproduction of Sir William Broadbent's Harveian and Lumleian lectures and was published at the frequently expressed wish of his old pupils. Since the first edition it has been amplified and further enriched by the assistance of his son, Dr. J. F. H. Broadbent.

The work opens with a chapter detailing the relations of the heart to the chest wall, an account of the movements of the heart, and an excellent *résumé* of the methods of the clinical examination of the organ. Next the pulse is fully considered and the term "arterial tension" as used by the authors is explained. We are glad to see that hypertrophy of the muscular coat is distinguished from arterio-sclerosis and we may mention that Sir William

Broadbent has never failed to find the former in the cases of granular kidney which he has examined. Diseases of the pericardium follow and here it is pointed out that the increase in the cardiac dulness observed is in the majority of cases due to cardiac dilatation and not so much to the effusion. The section on endocarditis is very complete. In the treatment of the malignant form not much stress is laid on the results that may be hoped for from antistreptococcic serum. Of course, there must be a certain amount of chance as to whether this will counteract the particular organism involved. Still, the only cases of recovery that we have known have been under the use of this remedy.

The account of valvular lesions comes next and is very complete. The attention of the student is directed to the valve affected and the relative danger of each particular lesion, and with respect to this the authors hold that as regards aortic stenosis the danger is greater than has been supposed and that although this lesion is not so serious as aortic incompetence or mitral stenosis yet it is more so than mitral incompetence. With regard to aortic regurgitation, when acquired late in life the prognosis is unfavourable, especially when it is due to syphilitic disease of the aorta invading the valves. Should aortic stenosis supervene in addition it may act as a palliative agent, the risk of undue dilatation being diminished when the patient is still young, so that further hypertrophy may take place. Mitral incompetence is held to be the least serious of all valvular affections, whilst mitral stenosis stands next to aortic regurgitation in the order of gravity. The account of the changes which the mitral murmur undergoes in mitral stenosis is one of the best with which we are acquainted. With regard to the vexed question of administering digitalis in aortic incompetence the writers hold that in the absence of mitral symptoms this drug can rarely be of service and may undoubtedly do harm.

In writing on the question of sudden death in heart disease it is pointed out, as regards valvular lesions, that aortic regurgitation constitutes the only dangerous lesion with respect to this catastrophe. The chapters on the prognosis of valvular disease embrace the whole subject very completely and will repay the most careful attention. With regard to the general treatment of the affections the indications for the Oertel and Schott method are judiciously set forth and in the section on the treatment by drugs the action of, and indication for, digitalis are clearly pointed out. We next come to the consideration of the structural changes in the heart—namely, hypertrophy and dilatation, both viewed generally and more especially with reference to their occurrence in the right ventricle. Some excellent plates illustrate the chapters on the diseases of the myocardium.

With regard to that serious disease, angina pectoris, it is pointed out that the distressing and agonising symptom pain is in truth a blessing in disguise, inasmuch as were it not for the warning thus given of an impending attack and the cessation of exertion thus enforced the patient would die suddenly without any warning. The explanation of Huchard—attributing the affection to ischæmia of the heart—is held to be the most satisfactory one yet advanced. The work concludes with an account of aneurysm of the aorta. Here space will only admit of our drawing attention to the opinions of the authors as regards treatment. The most important measure is rest; next the method of feeding, that is to say that the amount of liquid must be reduced to a minimum, the food must not be too bulky, and the states of repletion or depletion must be avoided. As regards drugs, iodide of potassium has been found to have an undoubtedly favourable action. Ergot, the use of which was practised by Sibson in large doses, diminishes the pulsation. The authors do not speak very favourably of Lancereaux's method by the injection of gelatin and do not

recommend it. This we venture to think is rather too sweeping a condemnation of this means of treatment. Dr. Guthrie Rankin of the Seamen's Hospital has narrated some striking instances of the good results following the injection of gelatin. The authors recommend in its place the administration of chloride or lactate of calcium in addition to the limitation of the amount of fluids. In any case satisfactory results can only be expected when the aneurysm is saccular. In conclusion we can confidently recommend this interesting work as affording very useful lessons to the student of cardiac pathology.

International Clinics. Edited by A. O. J. KELLY, A.M., M.D., Philadelphia, U.S.A. Vol. III. Fifteenth Series. 1905. London and Philadelphia: J. B. Lippincott Company. Pp. 302.

THIS volume contains 23 papers on various subjects grouped under the headings of Treatment, Medicine, Surgery, Neurology, Dermatology and Syphilis, Rhinology, Ophthalmology, and Pathology. Many of them are of the nature of clinical lectures and contain a useful *résumé* of the current views on the subject dealt with, embodying the author's experience without containing anything strikingly novel, but in not a few some original observations or practical suggestions are set forth. Space will not permit more than a passing reference to some of the more important of these. Dr. George C. Johnston of Pennsylvania contributes a copiously illustrated article on the Therapeutic Uses of the Roentgen Rays or Radiotherapy, which he presents in a sanguine light for the treatment of a variety of skin diseases and malignant disease, concluding with a number of aphoristic recommendations. Detailed practical instructions for the application of the treatment are given. Dr. Albert Robin of Paris, in a short paper on the Action of Metallic Ferments on Metabolism and their Effects in Pneumonia, brings forward some remarkable observations of somewhat heterodox character. It has been stated by Bredig and others that very weak solutions of certain metals prepared by electrolysis possess certain reactions like organic diastases and that these reactions are capable of acceleration or inhibition by agencies exerting similar actions on organic ferments. After injecting these dilute solutions into man, Dr. Robin concludes that metals in extreme subdivision are capable of exerting remarkable physiological actions out of all proportion to the amount of metal used, including an increase in nitrogenous metabolism, an augmented output of urinary indoxyl, raising of the arterial tension, and marked changes in the blood corpuscles. He is of opinion that such metallic solutions are destined to take an important place among therapeutic agencies. Dr. Robin gives very few details of his experiments so that it is impossible to criticise his results.

Dr. Henry Huchard of Paris supplies an interesting summary of the musculo-tonic and diuretic actions of formic acid and the formiates and although he does not subscribe to all the remarkable claims of Clément of Lyons in regard to their actions he is of opinion that these drugs have a powerful musculo-tonic action and he gives records of experiments with the ergograph demonstrating this. He further finds that the urinary excretion is rapidly and very markedly increased, notably the amount of urea. Professor Teissier of Lyons in an interesting article on the Opothropic Treatment of Renal Insufficiency gives some noteworthy observations on the use of various extracts and preparations of renal tissue in the treatment of certain diseased conditions of the kidney. The preparations used were glycerine extracts of kidney tissue and the pulp of the entire organ macerated. The serum from the blood of the renal veins of animals was also tried. Professor Teissier states that carefully used renal opotherapy affords a useful adjunct

to other means of treatment in renal inadequacy. Professor Alexander M'Phedran of Toronto recommends in the treatment of membranous colitis rest in bed and measures directed to allay the sectional spasm of the colon to which he states the pain is due. For this purpose he gives in severe cases a hypodermic injection of morphine followed by the administration of copious enemata. Dr. F. Parkes Weber and Mr. E. Michels of London record an interesting case of primary carcinoma of the extra-hepatic bile-ducts with severe jaundice, which was relieved by biliary drainage through the operation of intra-hepatic cholangiostomy.

In the section of surgery an apparatus is described by Dr. M. Brockcart of Ghent for the injection of paraffin by the "cold" process whereby certain disadvantages of the method are overcome. Dr. Thomas D. Luke of Edinburgh contributes a careful paper on the Use of Ethyl Chloride as a General Anæsthetic, with references to the fatal cases hitherto recorded. Dr. A. Rose of New York describes the use of carbonic acid gas in rhinitis which he considers to be a remedy of the first order in the initial stage of that disease and one capable of ameliorating the intensity of the symptoms in all forms.

Professor Richard Kretz of Vienna, in an interesting communication on the pathology of cirrhosis of the liver, comes to the conclusion that the essential and initial changes are parenchymatous in origin, and that the condition is to be regarded as a "recrudescence, chronic degenerative process of the liver, retarded by ingrowths of regenerating tissue."

This volume of the series of "International Clinics" worthily maintains the reputation achieved by its predecessors and constitutes a suggestive addition to current medical literature.

Précis de Laryngologie Clinique et Thérapeutique: Maladies du Pharynx et du Larynx. Par le Dr. P. LACROIX, Membre de la Société Laryngologique de Paris. With 182 figures in the text. Paris: F. R. de Rudeval. 1906. Pp. 620. Price 8 francs.

In spite of the special attention paid to the study of diseases of the throat there is no work on laryngology which is at the same time elementary and complete from the point of view of the student and the medical practitioner. Dr. Lacroix proposes to fill this gap by his "Précis de Laryngologie." The work comprises four parts. The first part is devoted to the general technique of pharyngoscopic, laryngoscopic, tracheoscopic, and bronchoscopic examination, and the diagnosis and treatment of laryngological affections. The second part deals with the pathology of the pharynx, and the third with that of the larynx and sub-glottic region. In the fourth part, which is entitled "Syndromes Laryngiens," the author considers the symptomatology of laryngeal dyspnoea, hæmoptysis, guttural cough, dysphagia, and affections of the voice and of speech. It is a complete synthesis of the two preceding parts.

"Essentially practical" must be the verdict of those who study this book. It is intended for practitioners and students, and is sufficient for both. The descriptions are clear, the reasoning is sound, and the directions are lucid. It is freely illustrated, the illustrations being essentially diagrammatic in character and the diagrams for the most part extremely good; but as it is occasionally impossible to convey by means of pen-and-ink diagrammatic sketches a clear conception, some of them are failures. As examples, we may take the sketch of acute tuberculosis of the isthmus of the pharynx and the lips of the uvula, and voluminous granular papilloma of the lingual tonsil. The book is a cheap and useful guide to the study of laryngology and we believe that it will have a wide circulation.

LIBRARY TABLE.

A New Species of Trypanosoma found in the Blood of Rats together with a New Metrical Method of Standardising the Measurements of Trypanosomata. By Professor A. LINGARD, M.B. Durh., D.P.H. Cantab., Imperial Bacteriologist to the Government of India. *Through what Agency is the Trypanosoma Evansi carried over from one Surra Season to another?* By the same author. From the *Journal of Tropical Veterinary Science*, Vol. I., No. 1, January, 1906. Calcutta: Thacker, Spink, and Co.—The author observed some years later than July, 1877—the time at which Lewis detected flagellate organisms in the blood of apparently healthy rats—parasites intermingled with the trypanosoma *Lewisii* which appeared to possess a flagellum at either extremity. He was unable, however, with the imperfect method of staining flagellates then in use to demonstrate the hæmatozoa in specimens teeming with the recognised forms. During the past year he has again observed what appears at first sight to be a variety of trypanosoma, to which he has provisionally given the name of "trypanosoma Longocaudense." He has found this in many varieties of rats, never alone in the circulation but always concurrently with other well-recognised species of trypanosoma. Professor Lingard details the chief peculiarities of this form of organism immediately differentiating it from the trypanosoma *Lewisii* and has manifestly discovered a new species. In this interesting paper Professor Lingard gives a system of measurements of the several varieties of trypanosomata met with in the districts in which he has worked, a method which he has devised in order that some system of comparison of the mean measurements could be more easily made. He makes use of five measurements of different parts of the organism which, when severally added together, give the total length of the parasite. For the sake of comparison the mean of each of the five measurements of a large number of trypanosomata of any one species is first taken and later the percentage value of each measurement is calculated, taking the mean total length of the parasite as 100. The paper concludes with examples of measurements of the different varieties of trypanosomata. In the second paper Professor Lingard brings forward a question of considerable importance and interest to the owners of horses and cattle in India—namely, What is the agency called into requisition to allow the causal agent to be dormant from the termination of one surra season to the commencement of the next, and then to spring again into activity? for it is known that the usual type of surra in equines is fatal to these animals in a period of a few days to a maximum of two or three months. The author has for some time conducted an extensive series of experiments with the above object in view, the collated results of which have not hitherto been published. Spontaneous equine surra in the East has always been found to be an absolutely fatal disease due to the presence of the trypanosoma *Evansi* in the circulation of the affected animal and the period during which the malady runs its course is influenced by the strains of the hæmatozoon and also by the resistance offered to it by the affected animals respectively. Professor Lingard's researches demonstrate the following results: that in bovines when once the fatal form of the disease is established a rapid dissemination may occur through the agency of several species of flies; that in the case of camels different species of flies, Tabanidæ, Hippoboscidæ, and so on, play an important part in the dissemination of the disease, whilst in some instances the *Hematopinus* would appear to be the intermediate host by which the flagellate is conveyed from camel to camel; and that canines may help to bridge over a portion of the period during which the disease is not observed in equines and which is usually looked upon as the dormant season. The paper in question is a very

valuable one and is a proof of the good work carried on at the laboratory at Mukhtesar by the author.

Geschichte der Geburtshilfe. (History of Midwifery.) By Dr. HENRICH FASBENDER, Extraordinary Professor of Medicine at the University of Berlin. Jena: Gustav Fischer. 1906. Pp. 1028. Price 25 marks.—This monograph, the result of more than ten years' study of the subject by its author, will long remain, as aptly it has been termed by a German reviewer, a master work on the history of this branch of medicine. Professor Fasbender has set himself the task not only of revising the history of midwifery up to the time of the appearance of the first edition of Ed. Casp. Jac von Siebold's great work (1839) but also of completing it up to the present time. As he remarks in his preface, not only has the amount of material very markedly increased but modern methods of historical research are much in advance of those prevalent at the date of the appearance of von Siebold's work and the results obtained are correspondingly greater. The book consists of two main portions. The first, comprising 398 pages, gives a general survey of the history of midwifery, while the second, of some 600 pages, contains a special account of the history of midwifery from the middle third of the eighteenth century up to the commencement of the twentieth century. The author has been led to make this artificial division of the subject because at about the middle of the eighteenth century midwifery first became recognised as a separate branch of medical science, as distinct from general medicine and surgery. With the great advances which took place at this period in the practice of this speciality both the science and the art of obstetric medicine made considerable strides and these developments were accompanied by a very large increase in the amount of literature dealing with the various divisions of the subject. The second part of the book contains the history of the physiology and the dietetics, the pathology and the treatment, of pregnancy, labour, and childbed, and ends with a historical review of the various operations of midwifery. Professor Fasbender's fitness for the task which he has set himself has been amply demonstrated in his well-known work "Entwicklungslehre, Geburtshilfe und Gynaekologie in den Hippokratischen Schriften." Just as this previous work excels all its rivals in its clear presentation of the subject, sobriety of judgment, and in the widespread range of knowledge of the literature which it shows its author to possess, so the present monumental work, the outcome of a colossal amount of research and labour, must for the same reasons long remain the standard work of reference for all writers in this interesting field of medical history. It is a pity that the publishers have not issued the book in two volumes instead of one, as it is of inconvenient size, and the interest of the letterpress would have been much enhanced by the introduction of some illustrations.

La Guérison de la Tuberculose (The Cure for Tuberculosis). By Dr. PAUL FERRIER. Paris: Vigot Frères. 1906. Pp. 184. Price Fr. 2.50.—In this publication the author proclaims yet another special method of treatment for tuberculosis and explains the principles on which it is based. The keynote of the treatment is *calcification*. He starts from the pathological fact that healed tuberculous lesions undergo a process of calcification. From this he deduces that the difference between those patients who are able to withstand and to overcome the disease and those who succumb to it lies in the power of calcification of the former and his line of treatment consists in measures such as the administration of calcium salts, which should increase that power, and in the elimination of all factors which, in the opinion of the author, tend to diminish the power to calcify or actually to set up the opposite condition of decalcification. Insufficient power to calcify or a process of actual decalcification is supposed to be due either to a deficient supply of calcium salts in

the food, such as may occur in those districts in which the water supply lacks absorbable calcium salts, or to an excessive formation of acids in the system. According to Dr. Ferrier this supposed excess of acids in the system is chiefly caused by imperfect processes of digestion, leading to fermentation in the stomach with the formation of lactic and other organic acids. In consonance with this theory, therefore, the author puts his patients on a rigid diet, consisting chiefly of meat and bread and a small amount of vegetables. All acid ingredients, such as vinegar and lemon juice, are to be avoided and alcohol and fats are especially condemned as they paralyse the motor activity of the stomach and lead to stagnation and fermentation of the gastric contents. The meals must be so limited in amount and at such intervals that the stomach is completely emptied after each meal. This purpose is further aided by the administration of a glass of St. Galmier water half an hour before each meal. In addition, calcium salts are prescribed in cachets to be taken three times a day. The fundamental idea that a high degree of calcifying power may be an important factor in the healing of a tuberculous focus is itself suggestive and appears to open up fresh fields for careful investigation and research, but no one except the enthusiastic author of such an idea is likely to regard this ability to calcify as anything more than a possible factor in the highly complex processes involved in the reaction of the organism to the disease. As in the case of any other treatment Dr. Ferrier is, of course, able to cite a few cases in which his treatment has been followed by a rapid disappearance of all signs and symptoms of the disease, but there is a singular lack of any other attempt to support his views by a careful examination of facts and by serious research. It is an armchair theory without any adequate endeavour to test its value in the laboratory or the hospital, except by applying the deductions from it forthwith to the treatment of the disease. It is true that the author carried out a few experiments on guinea-pigs infected with tubercle but they did not lead to any definite conclusions. For the rest the theory is backed up by dogmatic statements and casual observations.

New Inventions.

THE "WITCH" DUST EXTRACTOR.

THE removal of dust from carpets, hangings, and furniture by means of the broom or brush is opposed to sanitary ideals. Such a method merely effects at its best the dislodgment of dust from one place only to fall upon another. In short, the carpet may be cleaned and may look brighter for the process, but the dust is only scattered and sooner or later appears elsewhere, as, for example, upon the mantelpiece, bookshelves, or pictures in the room. Moreover, the broom by no means removes the dust perfectly even from the carpet to which it is assiduously applied. At any rate, when suction is applied to the swept carpet a good deal more dust is seen to be extracted. This is very well illustrated in the application of the simple dust extractor known as the "Witch," a model of which has recently been submitted to us for trial by the Witch Dust Extractor Co. of Temple Row, Birmingham. The way in which this appliance works will be readily understood from an inspection of the accompanying illustration. It consists of a pair of exhaust bellows worked by foot to which is attached a length of hose and in its turn an "extractor" shaped like a flattened out speaking-tube. On working the bellows a strong suction takes place at the mouth of the extractor which rapidly withdraws the dust from the carpet over which the extractor travels. Some idea of the force of the suction may be gathered from the fact that ordinary pins find their way into the receptacle for the dust which is contained in the exhaust chest of the apparatus.

When fine flour is well rubbed into a carpet, even of heavy pile, the flour is completely removed. In the exhaust chest and connected with the hose is a detachable linen bag which serves to retain the finest dust as it is pumped from the carpet into the machine. The collection of "muck" in this bag is a revelation as to the filthy character of the dust which accumulates on the carpet. The dust is thus collected and not scattered and consequently

there is no need to cover up the ornaments and pictures in a room. Of course, the machine cannot be worked without expending some energy upon it but in practice it is said that servants prefer this kind of labour to the use of the broom and the result is much more satisfactory and decidedly cleaner in its application. This system threatens to do away with the unscientific and clumsy method of sweeping the carpet, and those who have any care at all for the application of sanitary measures in the house will express no regret that such is the case.

BRITISH MEDICAL BENEVOLENT FUND.

At the monthly meeting of the committee, held on June 19th, 21 cases were considered and sums amounting to £201 were voted in relief to 20 of the applicants. A legacy of £1000 was announced from the late Mr. Thomas Corbett, M.R.C.S. Eng., L.S.A., of Droitwich. Mr. George Eastes, M.B. Lond., F.R.C.S. Eng., was elected a member of the annuity sub-committee. Appended is an abstract of the cases relieved.

Widow, aged 53 years, of L.R.C.P., L.R.C.S. Irel. who practised in Birmingham and who died six months ago after some years of ill health which exhausted his means. No children. Recommended by Dr. I. G. Modlin. Voted £5 in one sum.

Wife, aged 43 years, of M.B., C.M. Glasg. Was deserted by husband some years ago and has supported herself since by letting lodgings but has been obliged to incur some small debts. Recommended by Dr. G. T. Beaton, honorary local secretary. Voted £5 in one sum.

Daughter, aged 62 years, of late L.S.A. who practised in Bucks and in London. Has maintained herself for several years as a housekeeper but is now unable to obtain a post. Recommended by Mrs. Snell. Voted £10 in two instalments.

Widow, aged 29 years, of L.R.C.P. Lond., M.R.C.S. Eng. who practised in Poplar. Quite unprovided for at death of husband a few months ago and had to sell furniture to pay funeral expenses and debts the death vacancy only realising £25. Has one child under two years of age and is at present living with her father but hopes shortly to obtain a situation. Recommended by Mr. Malcolm A. Morris, vice-president, Mr. H. W. Page, vice-president, and Dr. H. A. Caley. Voted £10 in two instalments.

Widow, aged 55 years, of L.S.A. who practised as a locum-tenent. Practically unprovided for at husband's death two years ago. No children. Health indifferent. Recommended by Mr. F. H. Knaggs. Voted £5 in one sum.

Daughter, aged 36 years, of M.D. Glasg. who was a surgeon in the Royal Navy. Applicant lost both her parents before she was three years old and has supported herself as a nurse for several years but is now ordered at least a year's rest on account of ill health. Recommended by Dr. W. J. C. Merry, honorary local secretary. Voted £12 in 12 instalments.

Widow, aged 65 years, of M.D. Edin. who practised in Lincolnshire. Income less than £10 a year. Children unable to help and applicant is in feeble health. Relieved twice, £17. Recommended by Sir Hickman Bateman, Bart. Voted £10 in ten instalments.

Daughter, aged 60 years, of late L.S.A. who practised for 50 years in a town in the North of England but lost his means through unfortunate investments. Has a small annuity from the North of England Governesses' Society. Tried to keep a lodging-house with a sister but was unsuccessful and had to sell a portion of the furniture to pay debts. Relieved eight times, £72. Recommended by Dr. C. J. Gibb. Voted £10 in two instalments.

Widow, aged 55 years, of M.B., C.M. Edin. who practised in Lancashire. No income; small earnings from needlework, but finds

difficulty in obtaining orders. A little help from son, aged 22 years, earning 25s. a week as a clerk. Relieved three times, £36. Recommended by Dr. Claud Muirhead. Voted £12 in 12 instalments.

Daughters, aged 46 years and 43 years, of late L.R.C.P. Lond., M.R.C.S. Eng. who practised in Wales. No income; endeavour to maintain themselves by knitting in the winter and by letting lodgings in the summer, but last year had an extremely bad season, only having their rooms occupied for seven weeks. Relieved seven times, £75. Recommended by Dr. F. T. Roberts, vice-president. Voted £12 in 12 instalments.

Widow, aged 43 years, of L.R.C.P., L.R.C.S. Edin. who practised in Essex. Six children, aged from 20 to 11 years, the four eldest being clerks earning a small weekly salary. Endeavours to keep a home for the family by the help of the sons and by taking a couple of boarders, one of whom has just died. Relieved three times, £36. Recommended by Sir Lauder Brunton, vice-president. Voted £12 in 12 instalments.

Daughter, aged 43 years, of late M.D. Edin., F.R.C.P. Edin. who was a university lecturer and examiner in midwifery. Has been in bad health for several years past but until recently was able partially to support herself; has now been quite incapacitated for some months and is dependent on a grant from the Royal College of Physicians of Edinburgh and the help given by this fund. Relieved eight times, £70. Recommended by Dr. Joseph Bell, honorary local secretary. Voted £2 in 12 instalments.

Daughter, aged 35 years, of late F.R.C.S. Eng. who practised in Bedfordshire. Has been laid up for more than a year with hæmorrhoids and phlebitis and is only just beginning to walk about again. Dependent on mother whose income is less than £1 a week. Relieved six times, £50. Recommended by Mr. G. Rice Ord. Voted £10 in ten instalments.

Daughter, aged 57 years, of late M.D. Edin. who practised in Devonshire. No income. Is allowed a small weekly sum by a brother but owing to constant ill health for the last three years it is not sufficient for absolutely necessary expenses. Relieved once, £10. Recommended by Dr. R. H. Paramore. Voted £5 in one sum.

Widow, aged 51 years, of L.R.C.P., L.R.C.S. Irel. who practised in London. No income. Has endeavoured to support herself by maternity nursing for several years but is now nearly blind. Relieved four times, £41. Recommended by Mr. J. P. Fennell. Voted £12 in 12 instalments.

Daughter, aged 46 years, of late M.R.C.S., L.S.A. who practised in Lancashire. No means and unfitted for permanent employment by epilepsy and general ill health. Relieved three times, £36. Recommended by Dr. A. M. Edge, honorary local secretary. Voted £12 in 12 instalments.

Widow, aged 41 years, of L.R.C.P., M.R.C.S. who practised in London. Was practically unprovided for at husband's death and for seven years has been housekeeper for a medical man who is now about to marry. Three children, aged 17, 16, and 15 years respectively, one being very delicate after rheumatic fever. Applicant proposes to take a small house to receive boarders and is promised every possible help by several medical men of her acquaintance. Relieved three times, £25. Recommended by Dr. James Galloway. Voted £15 subject to £45 being raised by her friends.

Widow, aged 45 years, of L.R.C.P., L.R.C.S. Edin. who practised in Sheffield. No income, and dependent on a son, aged 19 years, earning 18s. a week as a labourer, another son having just married, and a daughter, aged 16 years, having been obliged to give up work on account of ill health. Relieved eight times, £99. Recommended by Dr. W. Dyson. Voted £10 in ten instalments.

Widow, aged 58 years, of M.D. St. And. who practised in London. No means. Lets lodgings but has only one of her rooms occupied. Children unable to help. Relieved twice, £24. Recommended by Dr. G. Fielding Blandford. Voted £12 in 12 instalments.

Widow, aged 76 years, of M.R.C.S., L.S.A. who practised in Bucks. Four children, aged from 43 to 39 years, but three are deaf and dumb, and one epileptic also; the fourth is a teacher but at present has no post. Applicant has a small income but it is not sufficient for the maintenance of herself and her afflicted family. Relieved four times, £30. Recommended by Dr. A. Playne. Voted £10 in two instalments.

LEPROSY IN NEW SOUTH WALES.—The report of the New South Wales board of health on leprosy for the year 1905 has just been issued. It is signed by Dr. J. Ashburton Thompson, president of the board and chief medical officer to the Government of the State. On Jan. 1st, 1905, 17 persons remained under detention at the lazaret. During the year 12 persons were reported as being suspected lepers and of these seven were ultimately admitted to the lazaret. Two patients died during the 12 months under notice, one a native of New South Wales of European parentage and the other a native of England. An appendix attached to the report shows that the total number of persons admitted since 1883 when patients first began to be received is 103. Distributed under nationalities the account stands as follows: natives of New South Wales, 27, of whom 18 have died and 3 were released; of Queensland, 1, deceased; of England, 6, of whom 4 have died; of Ireland, 4, of whom 2 have died; of New Zealand, 1, deceased; of Fiji, 2, of whom 1 has died; of Germany, 2, deceased; of Belgium, 1, deceased; and of the United States of America, 1; all of these were whites of European descent. There were also 43 natives of China, of whom 14 have died and 29 have been returned to their own country; of India, 2, deceased; of the West Indies, 1, discharged in 1885; of Java, 1; of the Pacific Islands groups, 8, of whom 1 has died and 1 has been returned to his island; of New Caledonia, 1, deceased; of Zanzibar, 1, sent with Chinese to Hong-Kong at his own desire; and of Egypt, 1, repatriated; all of these were coloured people.

THE LANCET.

LONDON: SATURDAY, JULY 14, 1906.

Medical Attendance on the Working Classes.

THE very interesting and important paper by Dr. J. H. KEAY on Medical Attendance on the Working Classes, which was published in THE LANCET of July 7th, p. 15, is well calculated to direct attention to the actual conditions of a pressing and important problem which, as Dr. KEAY rightly declares, can only be solved by medical men themselves. It has been more or less coquetted with by philanthropists for many years and the general result of their endeavours has been to bring about a condition upon which it is impossible to congratulate any of the persons chiefly concerned, the public, the poorer patients, or the medical profession. In the metropolis according to figures attributed by Dr. KEAY to Sir HENRY BURDETT, some 2,000,000 of people, or roughly something like half the population, annually receive gratuitous assistance from hospitals or dispensaries. Without here discussing Sir HENRY BURDETT's authority for this figure, it cannot with any degree of probability be maintained that even a majority of 2,000,000 Londoners would be unable to pay a fee to a medical man. In provincial towns and rural districts the operations of hospitals are probably more strictly confined to suitable applicants, and the needs of the industrial populations are met by clubs and other organisations, some of them concerned with medical relief alone; while in others the medical relief is only one part, though always an important part, of the general operations of a society or an association. In the enormous majority of cases, moreover, it cannot be said that the payments made by members to their clubs, on account of medical attendance, or the payments made by the clubs to their medical officers, at all adequately represent the value of the services rendered, or the amount of work which these medical officers are called upon to perform. In certain rural districts the holding of club appointments, and even of Poor-law appointments, forms a traditional part of the natural functions of leading practitioners in the locality; but in towns the tendency is not necessarily in the same direction. It in no way follows that those who hold these offices may not be as capable or as conscientious as their neighbours, but the fact remains that they may not possess so high a local reputation; and their patients are often keenly alive to this circumstance and quite ready to avail themselves of it as an excuse, if not as a justification, for the slenderness of the payment which the "club doctor" is often forced to accept. In some cases, as our readers are only too well aware, clubs founded for the ostensible purpose of affording medical relief to the poor have been extended to embrace

persons who could not be so described; and these clubs have been conducted by the aid of active canvassing which has rendered them exceedingly injurious to the practitioners of the vicinity, whose patients, although well able to pay customary charges, have been tempted away by the bait of a small subscription and by the asserted merits of the medical man who has been secured, at the cost of a modest salary, to devote his skill to the healing of club members. Action of this kind has to a great extent been checked by the determination of the General Medical Council to regard the proceedings of the medical men connected with such clubs as "infamous in a professional respect," but there are undoubted difficulties attending such a settlement of the question. Dr. KEAY, however, utters a timely warning to the effect that medical men should be very careful in assuming or approving any position which may be interpreted as that of a trade rather than of a profession, or which might lead to the forfeiture of the high reputation for unselfishness which has been handed down to us by many generations of illustrious predecessors. He feels, and all, we think, must admit, that some of the most conspicuous of medical "reformers" have not always been sufficiently careful to keep themselves above suspicion in this respect.

The example of Germany is quite sufficient to show that it would be well within the powers of the industrial classes of Great Britain to support, and well within the powers of the medical profession to organise, a scheme of medical relief which would be far more effective than the present want of system as regards the sick, and far more satisfactory to the practitioners concerned in its administration. A serious impediment in the way is the abysmal, but we hope not the invincible, ignorance of the classes from whom the patients must be derived. The chief difficulties of treating the illnesses of the British workman, of his wife, and of his children are dependent upon the filthiness of the dwellings and persons of the patients and upon their frequent refractoriness to orders concerning rest, food, and other essentials. We want to see in our industrial districts a sufficient establishment of cottage or workmen's hospitals to which every local practitioner could send his patients and remain in attendance upon them, obtaining an increased average of successful treatment, and a shortened average duration of illness, from the conditions of an institution which would be largely educative in its character, and which would give a blissful experience of clean clothing, clean bedding, and clean food, to all the sick persons who were fortunate enough to find admission within its walls. Hospitals for the members of their body are maintained by the working classes in Germany, and their maintenance would be quite within the means of the same classes in this country. We believe that a start might be made, by the assistance of a combined effort on the part of the local medical practitioners, in any district in which labour was sufficiently abundant for the formation of large clubs, in which there were a few enlightened and influential employers who would assist with advice and perhaps with a certain portion of the preliminary outlay. We have no doubt that such cottage or workmen's hospitals would soon justify their presence and would afford full compensation for the cost of bringing them into existence. Their institution would abbreviate illnesses,

would lighten the load of sick pay, and would become a centre of sanitary education in their district. They would materially assist practitioners, not only by placing the sick in conditions favourable to their recovery but also by bringing them together in a convenient place and thus diminishing the labour of attendance upon them.

Dr. KEAY contemplates a possible extension of the principle of the Education Acts to illness and a provision of free medical treatment for the sick at the expense of public funds, either local or imperial. The late Sir BENJAMIN WARD RICHARDSON was fond of speculating upon such a possibility and often said with how much pleasure he would be content to be paid by the State and not by the patients who required his services. Something might perhaps even be urged on behalf of the Chinese system, under which the patient, according to tradition, pays a regular stipend to his medical adviser when in health, suspending payment when illness falls upon him. But in either plan difficulties might arise in bringing it into practical application. Under the system of State payment a popular medical man would have difficulty in defending himself against the attacks of importunate patients and might often be called upon for exertions beyond his powers. Under the Chinese system the medical man would at least require to guard himself against illnesses caused by excesses or insanitary practices and would rightly demand a large amount of control over the habits and proceedings of his flock, a far larger amount than he would ever obtain. For the present, at least, we are more likely to continue in this country upon the lines traced out for us by experience, and the problem before us is to find a means of so combining the possible payments of the comparatively poor as to make them into an aggregate sufficiently large to bear the cost of the aggregate of sickness falling upon the contributors. We believe that this object might be accomplished by a better and more intelligent adaptation of the club system, especially with the aid of a hospital system such as that which we have indicated above. We may, at all events, hope that the difficulties of the case will tend to diminish as time goes on, and that education will some day produce results in the shape of better national and individual sanitation, with a corresponding decrease of the burden which sickness now casts upon all classes of the community.

The Royal Victoria Infirmary, Newcastle.

ON Wednesday, July 11th, the Royal Infirmary, Newcastle, ceased an honourable existence of over 150 years and was re-born as the Royal Victoria Infirmary. His Majesty KING EDWARD VII. opened the new buildings in person and the stately ceremony, to which we just allude in another column, went to make the occasion one which should be memorable for ever in the old city of Newcastle. The history of the Newcastle Infirmary is of more than local interest, for it is, with the exception of the few hospitals in these islands the foundation of which dates from mediæval times, that of practically every hospital in the land. Founded during the eighteenth century to cope with the needs of a small town of some 20,000 inhabitants it gradually became obliged to minister to the afflictions

of the body inseparable from the daily toil of a huge industrial community, and in a book now before us,¹ a copy of which has been accepted by the KING, Dr. GEORGE HALIBURTON HUME has compiled a complete account of the rise of the infirmary, its trials, its successes, and its growth. "The onlie begetter" of the Newcastle Infirmary is as mysterious as is "Mr. W. H." and, like him, is known solely by initials—namely, "B. K." Over these initials there appeared in the *Newcastle Courant* of Jan. 5th, 1751, a letter which commenced as follows:—

"At a Time when so noble a Spirit of Charity is stirring amongst us, and, to the Honour of this Age and Nation, such great Encouragement is given to all charitable Foundations; when we see particularly Hospitals for the relief of the Sick Poor, which, of all the various Kinds of publick Charity, deservedly claim the first Rank, erected in almost all the large Towns in this Kingdom: That no such thing should ever be set on foot in this Town, is, I think, not a little strange and extraordinary.

"Certainly, if in any Place, London excepted, an Establishment of this kind is necessary, it must be so here. For where are there so great Numbers of Poor employ'd, or their Employments more dangerous, than in and about this Neighbourhood?"

The letter then goes on to plead for a hospital and the result was that in May, 1751, a house in the Gallowgate which had been hired was opened, after a religious service conducted by the Archdeacon of Northumberland, as an infirmary, when seven in-patients and four out-patients were admitted. The staff was as follows: Dr. ASKEW, Dr. COOPER, Dr. JOHNSON, and Dr. LAMBERT as physicians, while the surgeons were Mr. SAMUEL HALLOWELL and Mr. RICHARD LAMBERT who, if not "B. K.," is generally supposed to have instigated the writing of the letter. The chief provision previously to the opening of the Gallowgate Infirmary for the needs of the poor had been supplied by the "worthy Magistrates of the Town" who had allowed £80 per annum to four surgeons to visit the poor. After the starting of the infirmary the corporation gave a site for the erection of a permanent building, together with a donation of £100, but the £80 were reduced to £40. The foundation stone of the first permanent building was laid by Dr. BUTLER, the Bishop of Durham, on Sept. 5th, the site being then in the open fields.

Like most other hospitals in the eighteenth century and earlier, the infirmary was founded to improve the moral conditions of the patients as well as the physical, and in a set of rules dated 1801 patients were told that when they are "discharged cured they shall be strictly enjoined by the Chairman of the Committee, to return thanks to Almighty GOD in their respective places of worship and to the subscribers who recommended them." This formula was common to nearly all hospitals some hundred years ago, but an instance came under our notice showing that a modern spirit of materialism is growing up. At a hospital of ancient and pious foundation the patients were recently told that if cured they were to return thanks to GOD "and in any case, to the subscriber who gave them the letter"—a comically worded notice which has since been altered. Like other hospitals, too, the Newcastle

¹ The History of the Newcastle Infirmary, by George Haliburton Hume, D.C.L., M.D. Edin., F.R.C.S. Edin., Consulting Surgeon to the Royal Infirmary; price 10s. 6d., pp. 148, with portraits, plans, and other illustrations; Newcastle-upon-Tyne, Andrew Reid and Co., Limited, 1906.

Infirmary has from the time of its inception been confronted with the problems arising from overcrowding and from an insufficiency of income fully to provide the money for expenses. 50 years after its foundation—namely, in 1801—it was reconstructed and enlarged. Another 50 years went by and again a new wing was built called the Dobson Wing after JOHN DOBSON, the architect. In 1875 Dr. G. T. BEATSON, a recently qualified and enthusiastic disciple of LISTER, was appointed house surgeon and the antiseptic system of surgery, then on its trial, was introduced into the hospital under very favourable auspices. Dr. BEATSON, now surgeon to the Western Infirmary, Glasgow, was able to give first-hand information on all the details of technique, and so good was the result upon the surgical work of the hospital that the overcrowding became worse than ever, for patients flocked to obtain the benefits of the new method of treatment. Accordingly in 1885 a nominally temporary block of 50 beds was opened under the name of the Ravensworth Wards. This lasted for more than 20 years, when the Royal Infirmary entered upon its present stage. In 1896 the then Mayor, Mr. (now Sir) RILEY LORD suggested that the building of a new infirmary would be the best memorial of the sixtieth year of the reign of Her Majesty Queen VICTORIA that could be. Aably seconded by his fellow citizens he set himself to raise the sum of £100,000 and by the date of the Diamond Jubilee this sum had been secured, £20,000 of it having been contributed by the working classes.

Thus were laid the beginnings of the magnificent building which was opened on Wednesday by our KING. The work has not been without its difficulties. The question of a site was settled by the gift by the city of a plot of land near the Leazes but the question of more funds remained. Mr. JOHN HALL, however, in July, 1897, offered a sum of £100,000 as a contribution towards building and equipment, while in March, 1901, Mr. W. WATSON-ARMSTRONG (the present Lord ARMSTRONG) and his wife offered another £100,000 in memory of the late Lord ARMSTRONG. Thus all difficulties were overcome and in August, 1901, a contract was signed at a cost of £203,527 not inclusive of the engineering contract. The architects are Mr. W. L. NEWCOMBE and Mr. PERCY ADAMS, and perusal of Dr. HUME's book, to which we have already referred, as well as the columns of all the local newspapers, will show that in every detail the new hospital has been built and furnished with regard to modern hospital requirements. Of old time Newcastle took her part in many a stern fray. Scots and English fought for her possession and around her, while many a time between Durham and Newcastle "There was no town without it were closed, but it was brente." And now, in that great house of healing, English and Scots will fight, not against each other for the possession of a city built of dead stones but as brothers in arms for the living stones of the temple of humanity, against disease and sorrow and death. And here, too, will the memory of a great Queen, of a ruler who spared not herself for her people, be kept green, so that not of her alone but of the donors, whether rich or poor, who have given of their substance, of the physicians, the surgeons, the nurses, and of all who toil within its walls it may be said, "The just shall be had in everlasting remembrance."

The Prophylaxis of Sleeping Sickness.

THE alarming spread of sleeping sickness, or human trypanosomiasis, in Africa and the apparently hopeless prognosis when infection has taken place, render the establishment of effective preventive measures peculiarly urgent. The nature of the problems involved in the institution of such prophylactic regulations can be best realised after a summary of the principal facts in regard to trypanosomiasis. That flagellated protozoa can occur in the blood of vertebrates has long been known. A form occurring in frogs was described in 1843 by GRUBY under the name of *trypanosoma sanguinis* and the generic name of *trypanosoma* was thus instituted. In 1878 it was shown by EVANS that a similar parasite occurred in the disease of horses in India and other parts of Southern Asia known as surra. This parasite is named the *trypanosoma Evansi*. In 1895 it was shown by BRUCE that the tsetse fly disease or nagana was due to a parasite of the same character, now known as the *trypanosoma Brucei*. So long ago as 1898 NEPVEU described trypanosomes as occurring in the blood of man but the discovery only achieved the notice which it deserved after the parasites were indubitably demonstrated in the blood of Europeans in 1902 by Dr. J. E. DUTTON and Sir PATRICK MANSON. In the same year the discovery of trypanosomes in the blood of patients suffering from sleeping sickness by CASTELLANI and the subsequent confirmation of that observation by various authors gave a great impetus to the study of these peculiar protozoa. The form occurring in sleeping sickness is now known as the *trypanosoma Gambiense*. Most, if not all, of the trypanosomes at present known seem to require two hosts, one a variety of the tsetse fly by which they are injected into the second host—a vertebrate. At present eight varieties of tsetse fly are known and it is possible that other arthropoda may be the agent of infection in some forms of trypanosomiasis. The tsetse fly which is the infective agent in sleeping sickness is the *glossina palpalis*, that in nagana or tsetse fly disease being the *glossina morsitans*.

The life-history of trypanosomes is at present far from completely known, although sexual and asexual forms are described and the relations of these have been carefully studied in a trypanosome occurring in the little owl by Dr. FRITZ SCHAUDINN, the discoverer of the *spirochaeta pallida* in syphilis, whose recent death at the early age of 35 years leaves the study of protozoology sadly the poorer. The most usual form in which the parasite occurs in the blood is as an elongated organism about three times as long as a red blood corpuscle with a wavy lateral membrane and a long flagellum. A nucleus and a centrosome to which the name of blepharoplast has been applied are present. The terrible ravages wrought by this parasite may be realised when the figures are considered. It is calculated by Captain E. D. W. GREIG, I.M.S.,¹ that since 1900 in Uganda alone fully 100,000 natives have died from sleeping sickness, while Dr. J. L. TODD² estimates that from 400,000 to 600,000 deaths have occurred from that disease during the past ten years.

¹ THE LANCET, Jan. 27th, 1906, p. 226.

² Brit. Med. Jour., April 21st, 1906, p. 943.

In a paper of considerable interest and importance published in our columns³ Dr. TODD discusses very forcibly the probable causes of the spread of the disease and offers some practical suggestions for checking that advance. He points out that the disease spreads but slowly from an infected area unless it is carried by an infected person into other localities and further that in the Congo Free State the disease has spread along the main routes of communication and to a much greater extent since the country has been opened out by Europeans. The paper is illustrated by maps which demonstrate these facts in a striking manner and also show where imported cases have occurred in previously non-infected districts. Previously to 1884 sleeping sickness appears to have been practically confined to the Lower Congo and certain posts on the main river as far as Bumba, while at the present time it occurs along the whole Congo basin and also on the banks of some of its tributaries as well as about Lake Tanganyika and Lake Victoria Nyanza, while recently it has appeared on the western shores of Lake Moero. It has also broken out in the neighbourhood of Sierra Leone. Dr. TODD concludes that the uninfected areas of the Soudan, Northern Nigeria, German East Africa, and British Central Africa stand in the gravest danger of being infected. From the nature of things it follows that the rational form of prophylaxis would be the prevention of entry of infected persons into a district where glossina palpalis is known to exist and where the disease does not occur. For this purpose Dr. TODD suggests "the establishment of medical posts of inspection along the trade routes leading from infected to uninfected districts and the removal of infected persons from posts in uninfected districts to places already infected."

Owing to the prolonged course of the disease in many cases, even as long as three or four years, it is obviously necessary if these recommendations are to be carried out effectively that some means of early diagnosis should be available. Fortunately, in the palpation and puncture of glands as used by Dr. TODD and the late Dr. DUTTON, such a diagnostic means has been found. After an examination of 6358 apparently healthy negroes of all ages and both sexes they came to the conclusion that every negro whose cervical glands are enlarged without obvious cause must be considered to be a case of trypanosomiasis until the contrary is proved. It has been shown that trypanosomes can easily be demonstrated in the fluid drawn from such glands by a hypodermic syringe and Dr. DUTTON and Dr. TODD found that though not infallible this measure afforded an efficient means of diagnosis. It is obvious that we are face to face with a real danger and that there is need for some endeavour to stop the advance of the disease. The cause is now known and the means of combating infection are apparent; it is, therefore, a matter for the administration of the areas in danger of infection to deal with. Neglect to carry out preventive measures must inevitably result in a loss of life among the great native populations concerned alarming to contemplate, especially when it is recalled that the disease has practically depopulated some of the districts in which it has appeared. Moreover, the danger to Europeans

engaged in these districts is one to be borne in mind, since they possess no immunity to the disease other than that offered by the greater amount of clothing worn, and the recent lamented death of Lieutenant FORBES TULLOCH, R.A.M.C., from trypanosomiasis serves to emphasise this danger. We may express the hope that the authorities will carry out without delay some such measures as those outlined by Dr. TODD.

Annotations.

"Ne quid nimis."

GEORGE BUCHANAN AND THE HEALING ART.

George Buchanan was born 400 years ago, and the University of St. Andrews has just commemorated the anniversary of its most distinguished alumnus. Sir Douglas MacLagan, in a note to his "College Lays," reviewed in these pages,¹ refers to the tradition that the "cap" imposed on the heads of successful candidates for the *summi in medicina honores* at Edinburgh was made out of the pantaloons of George Buchanan. If such be the case, the graduates of the "Grey Metropolis" may be excused for feeling a certain pride in having passed into the humanest of professions under cover (so to speak) of "the greatest of the Humanists," of one who, whether in prose or verse, never fails to speak in the highest praise of the healing art, who even in his "Rerum Scotticarum Historia," or in his "De Jure Regni apud Scotos," or in drama, elegy, lyric, and epigram goes out of his way to eulogise a profession fraught with benefits appreciated by all good citizens — by none more than by enlightened laymen like himself. Last week academic Scotland has been celebrating the quatercentenary of his birth, thus making tardy amends to one whose *manes* have been even more neglected than the living man, and doing something, let us hope, to deflect the point of the witty Irish scholar's home-thrust: "The Scots are more given to boast of Buchanan's name than to read his writings." All that is characteristic of his compatriots — "the good and the not so good" — was represented in George Buchanan. He had the love of knowledge for its own sake which made him from his boyhood a searcher, Ulysses-like, after fresh experiences, passing from college to camp, from professorial chair to diplomatic chancery, letting slip no opportunity of learning, or of turning to account what he had learned, till the wandering fit — or shall we say the *mania errabunda?* — left him, a returned exile, to spend the evening of his days in his native Scotland and to repay that "arida nutrix" (if not "injusta noverca") with services which ought to have put her to the blush. The world on which he entered was writhing in the strait-waistcoat of scholasticism from which it had to be rescued by scholarship, and Buchanan, like Erasmus and the other Humanists, set himself to the congenial task. There reigned an Aristotelianism which was far removed from Aristotle, inculcated in a Latinity which was not Latin, both protected by a Church which had declined from its early purity to become the nursing-mother of obscurantism in the academic sphere and of despotism in the political. Panoplied in the learning of the Sorbonne, a French university man, "finished to the finger-nail," combining the lore of Erasmus and the humour of Rabelais with a poetic vein and a gift of verse denied to both, Buchanan served in the anti-scholastic campaign under a flag inscribed —

"Antiquam exquirite matrem,"

³ THE LANCET, July 7th, 1906, p. 6.

¹ THE LANCET, Nov. 27th, 1886, p. 1025.

and with all available equipment (satire by preference) he recalled the iron age of deductive logic with its verbal *Spinnageneberet* to the golden age of untrammelled thought and genuinely inspired genius, constraining the world (as in the tale of Aladdin) to exchange the feeble, fustid lamps of the new order for the bright, fragrant lamps of the old. In this enterprise he developed and displayed a genius for sarcasm, for "irony, that master spell," which carried strongholds and levelled bulwarks impregnable against other artillery—indeed, to this day he has his equal to find in a combination of delicate raillery and high-wrought invective which suggest Horace and Juvenal rolled into one. The "Fratres Fraterrimi" and the "Franciscanus" remain among the masterpieces of satirical production and can never be left out in any roll-call of the forces to which the Renaissance owes its most salutary and enduring conquests. This is no place to re-open the embittered controversy as to his relations with his Queen, Mary of Scotland, and we may pass on to his signal services to education, services which every instinct of his nature urged him to render, lover of ingenuous youth as he was and possessed (as one who knew him well puts on record) "*eá ingenii dexteritate ut cum pueris repuerascere et ad omnes omnium ætatum usus modeste et sapienter sese accommodare et vellet et posset*" (with such nimble flexibility of mind, that with boys he had the power, as he had the will, to become a boy again and, with equal modesty and wisdom, to adapt himself to all the requirements of any stage of life). What a subject for a painting does he not furnish by his latest attitude when in his 77th year he—the great Humanist, Professor, and Diplomatist—was seen from his death-bed teaching a little boy his alphabet, a, b, ab; e, b, eb! Old Chaucer's immortal line on the Oxford clerk—

"And gladlie wolde he lerne and gladlie teche"—

has had no finer exemplar than George Buchanan who, holding all knowledge in reverence, knew no greater delight than imparting it and who (to conclude with what we set out by remarking) had a specially "warm side" for the medical art, dwelling fondly in his great history on the proficiency of the ancient Scottish kings and nobles in the treatment of the wounds which they were so prone to inflict, and commemorating in a lovely poem in the Ovidian distich the tender care and skill with which he was cured of a severe (and admirably described) attack of the "morbus articularis"—

"Sæpe mihi medicas Groscollius explicat herbas
Et sæpe languentem consilioque iuvat;
Sæpe mihi Stephani solertia provida Carli
Ad mala præsentem tristitia portat opem."

Characteristically enough, physicians have been among his greatest eulogists and most effective commentators from Guy Patin and Jean Pincler in his own century to Arthur Johnston in the century following, and so on to Robert Sibbald, Archibald Pitcairne, Tobias Smollett, and "Zeluco" Moore in the next. Francis Adams and Sir James Mackintosh may be mentioned as among his ardent admirers in the nineteenth century; and in this, not yet in its teens, on the occasion of the 400th anniversary of his birth, we venture to offer this modest *immortelle* to his *mancs*.

THE MEAT OF THE PEOPLE.

Few people are aware when ordering a joint of meat at the butcher's how many various sorts of meat can be purchased in the London market. The ordinary housewife orders a sirloin of beef for the Sunday dinner and makes no inquiry as to its origin, and is also most likely absolutely ignorant of the fact that it may be anything but English beef. Even the English beef coming into the London markets varies much in quality from the prime Scotch ox or heifer beef, down to that from plain cows, which is quite wholesome though poor

in quality, and is chiefly used for sausages. Four-fifths of the meat sold in the London market is of foreign origin and ranges in quality. Thus there is the best United States beef brought over in a chilled, not frozen, state (this beef is preferred by many English people to that of home origin and is largely used in London); then there is the Canadian beef brought over alive and killed at Deptford Market, the Dutch brought over here fresh, the New Zealand and Australian beef which comes over here frozen, and the Argentine meat which comes over in a chilled state. All these different kinds of beef can be bought in the London shops under the generic name of "beef" and as very few people know enough about beef to enable them to inquire as to its origin it is practically sold as English meat. The same arguments hold good as to the sale of mutton and of lamb. How many housekeepers when they see the advertisement "Canterbury lamb is now in season" know that Canterbury in New Zealand, not Canterbury in Kent, is referred to? Frozen mutton can be carefully thawed and made to look like English mutton and can be, and is, sold as such. THE LANCET has always raised its voice against substitution in any form and the selling of foreign meat without declaring it to be such is substitution. It is not contended that foreign meat, frozen or otherwise, which has been subjected to proper inspection is not fit for food, or is even much inferior to English meat, but to sell it without declaring it to be of foreign origin is not fair to the public. In one large firm of co-operative stores in London attention is drawn to their price for meat being higher than at other stores, on account of the fact that they sell exclusively British meat.

THE RELATION OF FERTILITY IN MAN TO SOCIAL STATUS.

DURING the last few years the question of the physical deterioration of the population has greatly agitated the public mind and has elicited all sorts of opinions, being accepted by some as an undoubted fact and vehemently denied by others. The principal argument in favour of the existence of deterioration, or at least the argument that has attracted most attention, is the high percentage of rejections among recruits seeking to enter the army—young men to whom the recruiting sergeant has made no objection but whom the medical officers refuse on the ground of physical imperfections. To this the other side replies that the high proportion of rejections is illusory as an index to the condition of the population at large and that the recruits so far from being average samples of the wage-earning classes are for the most part mere wastrels whose physical and mental incompetence handicap them in the labour market. The arguments on either side are therefore incomplete and inconclusive, but apart from the rejections of recruits there are many data from which some inferences may be drawn as to the physical condition of the nation. There are, of course, the death-rates of various classes at various ages, the duration of life in selected classes as shown by the results of life assurance and annuity offices, the birth-rate, the marriage-rate, the proportion of persons following indoor and outdoor occupations, returns of able-bodied and sick paupers, lunacy returns, the consumption of certain articles of food and drink relatively to the population, and so on. Among these various factors in national well-being or the reverse none is more important than the fertility of the people and some of the questions herein comprised have been studied in a monograph¹ written by Mr. David Heron, being one of the memoirs issued from the Drapers' Company biometric laboratory in connexion with University College, London.

¹ Published by Dulau and Co., 37, Soho-square, London, W. Pp. 22. Price 3s.

Mr. Heron devotes his first ten pages to an exposition of his methods of computation, after which the influence of social status on the birth-rate is shown numerically by correlating the characters given in one of his tables. The coefficient of correlation is some number between 0 and 1. Unity marks a complete causal relationship; correlations between 0.00 and 0.25 may be spoken of as small; between 0.25 and 0.50 they are moderate; between 0.50 and 0.75 they are large; and between 0.75 and 1 they are very large. A negative correlation means that one variable decreases with the increases of the other variable. First of all he examines the influence exerted on the birth-rate by those characters which mark ease and culture. He finds accordingly that the correlation between the proportion of occupied males who are engaged in professional occupations and the birth-rate is

$$= -0.781 \pm 0.051,$$

while the correlation between the number of female domestic servants kept and the birth-rate is

$$= -0.764 \pm 0.054.$$

In other words, in those districts where the professional classes are most numerous and where many domestic servants are kept, there the married women have fewest children. He then proceeds to consider the birth-rate as affected by poverty, pauperism, lunacy, pulmonary tuberculosis, cancer, and a great number of other conditions. With reference to the age of parents, he says that since emphasis is frequently laid on the postponement of marriage as one of the sources upon which the reduced fertility of the professional classes depends it is as well to note how very marked results can be associated with very slight differences in the mean age of reproductive wives. The only way of measuring the influence of age in this question of birth-rate and social status is to determine the coefficients of partial correlation. If r_{32} , r_{13} , and r_{12} are the correlation coefficients between three variables, then the partial correlation coefficient between the first and second variables for a constant value of the third is known to be

$$\frac{r_{12} - r_{13}r_{23}}{\sqrt{1 - r_{13}^2} \sqrt{1 - r_{23}^2}}.$$

But if the subscript 1 denote the birth-rate, 2 a character marking social status, and 3 the mean age of the wives of a district, then the above partial coefficient shows the reduction in the total coefficient (r_{12}) by taking a constant mean age of the married women. The correlation between birth-rate and mean age of wives was found to be

$$= -0.834 \pm 0.040.$$

The general inference from Mr. Heron's investigations is that postponement of marriage is not the sole reason why the better element in the community has at present the lower birth-rate.

GANGRENE OF THE LUNG AFTER SUBMERSION.

THOUGH the condition of the body of persons drowned has been the subject of numerous minute studies by medical jurists the consequences which may follow in persons who have escaped from drowning have received little attention. One of the most important of these is broncho-pneumonia. At the meeting of the Société Médicale des Hôpitaux of Paris on April 27th M. André Bergé reported a case in which pulmonary gangrene resulted.¹ A woman, aged 31 years, attempted to commit suicide about midnight on Jan. 30th, 1906, by throwing herself into the Seine. On contact with the very cold water the woman, who could swim, called out and endeavoured to maintain herself above water. She was carried by the very rapid current about 100 metres before she was rescued. She lost consciousness and the last thing she remembered was a violent pain in the

chest. On recovering consciousness she vomited some water tinged with blood. She was taken to hospital about 4 A.M. Her face was congested and she was still in a state of mental obtundition. On Jan. 31st she was perfectly conscious and complained of pain in the right side. There was a frequent dry cough but nothing could be heard on auscultation. The temperature in the morning was 99.8° F. and in the evening 101.3°. In the left eye was a large subconjunctival hæmorrhage the result of the congestion of the face. On Feb. 1st the temperature in the morning was 102.1° and in the evening 103.4°. There were pain in the right side of the chest and slight diminution of the resonance and vesicular murmur at the right base. On the 2nd some viscid mucus was expectorated. At the right base the vesicular murmur was absent. Bronchial breathing with, after coughing, fine subcrepitan râles was heard. The vocal fremitus was everywhere too feeble for purposes of examination. Two exploratory punctures in the dull area did not yield any fluid. The symptoms began to diminish on the 8th and from the 9th to the 12th the temperature was normal. On the 13th the temperature rose again to 103.1°. On the 14th there were pains at the left base and dullness at its lower part behind. The vesicular murmur diminished and disappeared in the dull area and the vocal resonance was lost. There was a dry cough with a little expectoration of mucous. On the 17th the morning temperature was 103.8° and the evening 104.5°. Two exploratory punctures were made with negative results. On the 28th the breath became very fetid and greyish muco-purulent frothy sputum with a putrid odour was expectorated in abundance. The signs at the left base, occupying about the lower third of the lung, remained the same. At the right base some dullness persisted and the vesicular murmur began to return and was accompanied by subcrepitan râles. The sputum contained a varied flora—leptothrix, long bacilli, short bacilli, micrococci, and yeasts. On March 1st the fœtor of the breath and sputum became intermittent. On the 4th there was some blood in the sputum. On the 8th some subcrepitan râles were heard at the left base. The temperature became normal on the 9th and recovery followed. M. Bergé thought that the entrance of water charged with septic germs into the air passages produced a focus of broncho-pneumonia at the right base and a symmetrical focus of gangrene at the left.

THE ADULTERATION OF BUTTER.

WE understand that the report of the Select Committee of the House of Commons appointed some months ago "to consider whether any, and if so what, further legislation is required in order to secure the better conduct and control of the trade in butter and butter substitutes" has been laid upon the table. The recommendations of the committee would appear to imply that its members recognise that some control is needed further than that provided by the analysis of samples secured under the provisions of the Sale of Food and Drugs Act. In these columns we have referred more than once to the increasing difficulties of the analyst in regard to differentiating one fat from another. When an analytical difficulty is admitted it is obvious that some other machinery must be started to protect the public from fraud. The committee evidently realises this and recommends the appointment of inspectors who should have the power to enter any premises where a reasonable suspicion arises that butter is blended, re-worked, or adulterated, or where a stock of adulterated butter is kept. Similarly, the storing of foreign fats, animal or vegetable, should not be allowed, it rightly suggests, in any registered butter-making premises. No butter should contain more than 16 per cent. of water and the same limit is suggested for margarine. As regards the trade in milk-blended butter or butter substitutes the committee sees no

¹ THE LANCET, May 12th, 1906, p. 1353.

reason for prohibiting it but it recommends that all butter substitutes or substances containing butter fat (not being margarine) should be sold under a name approved by the Board of Agriculture, provided that such a name shall not be calculated to prejudice the sale of the article. An honest label, therefore, seems practically to sum up the committee's recommendation if we except the limitation placed upon the maximum amount of water that is to be allowed. The principle of registration and inspection when applied to the sources of production in the way suggested should effect, it seems to us, a very salutary check upon the large amount of chicanery which exists in the butter trade at the present time. If the system should prove to work satisfactorily it is obvious that the responsibility for fraud ultimately detected by the analyst under the Sale of Food and Drugs Act will be fastened absolutely on the shopkeeper. In this connexion it may be pointed out that the adulteration of tea has been practically stamped out not by the operations of the Sale of Food and Drugs Act but by the examinations made at the port of entry by the Customs officials. It follows that if tea bought at the shops proves to be adulterated the fraud has been perpetrated by a middleman somewhere. As a matter of fact, tea is seldom examined by the public analyst and when it is it usually proves to be genuine.

THE DISPENSARY TREATMENT OF PULMONARY TUBERCULOSIS.

IN the Nobel lecture on Tuberculosis published in our columns on May 26th¹ Professor R. Koch emphasised the value of the excellent suggestion of Professor Calmette that dispensaries should be organised to afford relief, advice, and assistance to those sufferers from tuberculosis who though too advanced for treatment in a sanatorium were yet able to do a certain amount of work. He pointed out that more than 50 such dispensaries or "care stations" had been established in Germany, while the scope of their usefulness had been extensively widened under the direction of Pütter and Kayserling. Professor Koch regards these "care stations" as one of the most powerful agencies in the fight against tuberculosis. We publish in another column a letter of considerable interest from Dr. D. B. St. John Roosa of New York, giving an account of the work of the New York Post-Graduate Medical School in illustration of another use that may be made of dispensaries in the treatment of pulmonary tuberculosis. The idea originated with Dr. John F. Russell of endeavouring to treat early cases of that disease for whom sanatorium treatment was not obtainable while the patients continued to perform their daily work. Great care has been exercised in the selection of patients for this treatment and the following rules have been made. The patients must be able to earn their own living and to obtain a sufficiency of ordinary food. They must have early signs of actual tuberculosis, confirmed by laboratory investigations, but no signs of cavity formation or of extensive disease and must not be the subjects of any other serious disease or complication. They are required to attend at the dispensary every morning and evening—that is, before and after their day's work. They are given carefully graduated doses of mixed fats in the form of an emulsion prepared by Dr. Russell, containing 42 per cent. of fat made of beef-fat, cocoonut, peanut, and olive oil in equal parts, with about two drops of oil of cloves added to each ounce of emulsion. No supervision of the patient's food, clothing, or occupation is exercised but careful directions as to personal hygiene and the disinfection of sputum are given. In addition to the emulsion a fine pulp prepared from raw vegetable is also now given to the

patients and this is said to lessen the need for purgatives entailed by the fatty super-alimentation and also to assist the action of the fats. Dr. St. John Roosa states in his letter that the results obtained have been encouraging and that in the course of the eight years the system has been in operation 55 apparent cures have resulted; unfortunately, no details are given of the total number of cases that have been under treatment. Since 1905 an in-patient department has been added to the dispensary, where eight patients may be treated. A similar dispensary has been started in Richmond, Virginia. The special features of the dispensary at the New York Post-Graduate Medical School seem to be the care taken in the selection of the patients and the daily administration of fatty and other foods under the direct observation of the dispensary authorities, the hours of attendance being so arranged as to allow the patients to carry on their occupation. It is obvious that the cases treated are just those for which sanatorium treatment offers the best chance of ultimate recovery and thus the dispensary should only be used for cases which it is impossible, for domestic or pecuniary reasons, to send to sanatoriums. It is, however, a method which is worthy of being carried out elsewhere, since it offers another field of usefulness to the out-patient department of dispensaries in the treatment of tuberculosis, and since at present it is not possible to obtain sufficient sanatorium accommodation for all suitable cases it affords a means of dealing with some of the surplus cases. In districts where "care stations" exist of the kind suggested by Calmette and approved by Koch, these institutions might with great advantage adopt somewhat similar methods for some of their cases.

THE PACKING AND TRANSPORT OF STRAWBERRIES.

IT is often said that it is well not to inquire too minutely into the incidents connected with the preparation or transport of our food if we desire our relish for it to remain unimpaired. Of course, the handling of food cannot be very well avoided, nor can its exposure to undesirable conditions be entirely prevented, but care can at least be taken to insure the cleanliest transport and manipulation possible in circumstances that are admittedly difficult. There is no excuse, for example, for pitching loaves on the pavement or for exposing fish or meat to the oftentimes malodorous air of the street. It is not our wish to detract from the delights of the strawberry, for it is a fruit which is very universally enjoyed at this season of the year and there is no reason for believing that the sound, ripe strawberry is not wholesome, but there is evidence on all sides that it is peculiarly exposed to contaminating influences. Strawberries more or less wet are hawked on barrows in the street and there is no need to enlarge on the favourable sticky surface which the fruit presents for catching air-borne poisons. Quite recently we saw a large consignment of strawberries being unpacked from a train consisting of cattle trucks. It is to be hoped that the trucks had been carefully washed before the strawberries had been placed there. Most of the baskets were without lids and the strawberries were in many cases moist and in a condition well adapted for the adherence of dust. The dust of a not too clean cattle truck is not likely to be antiseptic and, what is worse, may easily be infected with tubercle bacilli considering that tuberculosis is a disease to which cattle are liable. Surely if cattle trucks or horse boxes must be used they ought to be most scrupulously cleaned out and disinfected before strawberries in uncovered baskets are placed in them. In the example which we quote the trucks did not appear to

¹ THE LANCET, May 26th, p 1449

have undergone any special cleaning at all. It is a wise precaution to wash strawberries in perfectly clean water before they are eaten. Such treatment does not injure the flavour of the fruit in the least. The man who carefully washes his lettuce or watercress because he thinks that pathogenic entities may be conveyed by them may as well neglect this precaution if he omits in the case of the strawberry the same simple process.

THE PHYSIOLOGICAL ACTION OF ETHYL CHLORIDE, ETHYL BROMIDE, AND ETHYL IODIDE, AND OF SOMNOFORM.

ALTHOUGH some of the anæsthetics mentioned in the title, particularly ethyl chloride, have now been in use for some years, and although considerable clinical experience has been accumulated, yet very little experimental pharmacological work seems to have been performed with these drugs. The June number of the *Bio-Chemical Journal* contains a contribution to the subject by Dr. W. Webster, lecturer on anæsthetics in the Manitoba Medical College. The experiments were conducted upon dogs, cats, and frogs, which were anæsthetised in the first instance with ether, chloroform, or the A.C.E. mixture, and sometimes, in addition, by the intravenous or subcutaneous administration of morphine. Ethyl iodide was tested only for the purpose of making the investigation more complete; its low volatility and nauseous odour would prevent its use as an anæsthetic in the human subject. Dr. Webster finds a remarkable uniformity in the qualitative effects of these drugs. Their physiological action differs in degree only, depending simply on the volatility of the drugs. The presence of methyl chloride does not appear to affect the results. With small doses the respiration is increased in frequency and depth; with larger doses it is diminished in both these respects. When very large doses are administered respiration may cease entirely some considerable time before the heart stops. The blood pressure is slightly raised with small doses of these drugs but larger doses produce a depression with or without a small preliminary rise. These effects occur with intact vagi, with both vagi cut, after full doses of atropine, and after nicotine. The drugs do not paralyse the vagus nerve endings. It is possible to obtain full action of the vagus when the animal is deeply under the influence of the anæsthetics. Their action upon the circulatory system appears to be almost entirely directly upon the heart. Dr. Webster points out that the use of atropine is contra-indicated in cases of an overdose of these anæsthetics. In the case of two animals, one of which was being anæsthetised with ethyl chloride and the other with ethyl iodide, rapidly fatal results occurred after the administration of atropine with an amount of the anæsthetic which in the absence of atropine had only produced a slight effect. The investigation has confirmed Mr. Sydney W. Cole's statement as to the value of artificial respiration in cases of an overdose of these anæsthetics.¹ In several instances Dr. Webster restored an animal by artificial respiration after voluntary respirations had ceased for from 30 to 90 seconds and the blood pressure had fallen almost to zero. These workers are in agreement also as regards the necessity for keeping a careful watch over the respiratory movements in using somnoform to avoid the great danger of paralysis of respiration. But as regards the effects of ethyl bromide and somnoform on the vagus their results are diametrically opposite, as is pointed out in an appendix to the paper by Dr. Swale Vincent. The tracings given by Dr. Webster show conclusively that full vagus effects can be obtained when the animal is completely under the influence of the drug.

¹ The Physiological Action of Ethyl Bromide and of Somnoform, by Sydney W. Cole, M.A., *Brit. Med. Jour.*, June 20th, 1903, p. 1421.

Mr. Cole, on the contrary, found that ethyl bromide paralysed the vagus terminals and his observation applied equally to ethyl chloride, ethyl iodide, and somnoform.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE sixty-fifth annual meeting of this association will be held on Thursday and Friday, July 26th and 27th, at the rooms of the association, 11, Chandos street, Cavendish-square, London, W., under the presidency of Dr. Robert Jones. Dr. Jones will deliver his presidential address at 2 P.M. on Thursday, after which Dr. Joseph S. Bolton will read a paper entitled "The Prefrontal Cortex Cerebri," with lantern plates. On Friday morning at 11 o'clock, Dr. F. W. Mott will read a paper entitled "The Effects of Alcohol in Hospital and Asylum Practice." Dr. A. Helen A. Boyle will narrate "The History of an Unusual Case of Murder"; and Dr. Edward N. Brush of the Sheppard and Enoch Pratt Mental Hospital, Maryland, U.S.A., will give a Description of the Method of Admission into, and Treatment in, the Hospital, also of the Founding and Organisation of the Hospital. On the afternoon of this day Mr. M. J. Nolan will read a paper entitled "On the Possibility of the Limitation of Lunacy by Legislation"; Dr. W. F. Menzies will read a paper entitled "Tuberculin Diagnosis"; Dr. Robert Pugh will read a paper entitled "The Relation of Goitre to Insanity"; and Dr. Edwin S. Pasmore will describe a Method of Taking "Family Histories." Facilities will be afforded by the London County Council to members on Saturday morning, July 28th, between 10 A.M. and noon, for visiting the London County Council electric power (52,000 horse power) generating station at Greenwich. The annual dinner of the association will take place on Thursday, July 26th, at the New Gaiety Restaurant, Strand, London, W.C., at 8 o'clock, and members are requested to notify their intention of dining to the present general secretary, Dr. Robert Jones, at 11, Chandos-street, Cavendish-street, London, W.

THE CONGRESS OF THE ROYAL SANITARY INSTITUTE.

THIS Congress opened on Monday last with a succession of social gatherings, there being receptions by the President, Sir Edward Fry, and the Lord Mayor of Bristol, an organ recital, and an inaugural address. This last, which was delivered by the President, was more of an ornamental than a practical character, and was listened to by an audience alive rather to the social than the scientific side of the gathering. The real work of the Congress began on the second day, Tuesday, with the meeting of the first section, that of Public Health, in the Victoria Rooms and two conferences—viz., those of municipal representatives and of engineers and surveyors to municipal and county authorities. With the exception of two papers read in the former of these conferences on the question of dealing with tuberculosis from an administrative standpoint, none of the subjects discussed had any special interest for medical men as such and we shall therefore confine our attention to those of the sectional meeting. The address of the president of the section, Sir William J. Collins, was in his absence read by one of the secretaries. In it Sir William Collins struck the keynote of the major part of the subsequent discussion, for owing, in the first place, to the non-appearance of the readers of some of the papers and in the next place to want of time two subjects only received adequate consideration. Sir William Collins's theme was the error of confining attention to the bacillus to the neglect of the soil, as a corollary of the variability

or instability of so-called species. He reminded his hearers that so long ago as 1884 he had maintained that in certain circumstances diseases commonly accounted specific might arise independently of contagion, in fact, *de novo*; that diverse diseases might have a common ancestry; that the same poison might produce different results in different individuals; and that there was in all nature a tendency for the common to become specific and the homogeneous to give birth to the heterogeneous; while in 1889 he enlarged further on the important part played by the soil, adducing the remarkable instances of the immunity of field mice to the bacillus of mouse septicæmia, fatal in three days to the domestic or white species, and the still stranger immunity of the Algerian alone among sheep to that of anthrax. He claimed the authority of Lord Lister, Dr. W. H. Dickinson, Sir Stephen Mackenzie, and Professor Virchow as supporting him in the reaction against the exclusive attention to the "germ theory" on the part of the "school of Pasteur and Koch," and described it as a return to the teaching of Chadwick, Southwood Smith, B. Richardson, and the pioneers of sanitary reform who thought only of pure air and water, of cleanliness and health. —

THE MANUFACTURE OF LEAD PAINTS AND COLOURS.

At the instance of the Home Office the Secretary of State has issued a draft of regulations which he proposes to make under Section 79 of the Factory and Workshop Act, 1901, for the manufacture of paints and colours in which dry carbonate of lead or red lead is used. These regulations are intended to supersede the existing special rules and embody the points agreed upon at a conference held between the representatives of the Home Office and manufacturers of paints and colours in February this year. It is stated that the draft regulations are such as to commend themselves both to employer and employed but to comply with the provisions of the Factory Act the regulations must be formally published in draft before being made. Any objection with respect to these draft regulations must be sent to the Secretary of State within 40 days of the date of their issue (July 9th). The regulations are divided in two parts, the first relating to the duties of the employers and the second to the duties of the persons employed. —

DISLOCATION OF THE MANUBRIUM FROM THE GLADIOLUS.

In the *Intercolonial Medical Journal* of Australasia for March Dr. W. A. James has published a case of a dislocation of the manubrium from the gladiolus—a very rare injury. A man, aged 51 years, whilst working in a sewer was pinned against the wall of a shaft by a mass of earth weighing about half a ton. The main impact took place on the upper part of the sternum. He was dazed but not rendered unconscious and half an hour later was able to ride to hospital on a tram-car. He was strapped up. On examination on the following day he exhibited a well-marked ridge across the sternum which was found to be the upper border of the gladiolus. Above this was a depression extending upwards for about an inch—the depressed manubrium, which was extremely tender. The manubrium was slightly tilted so that the depression was greater on the right side than on the left. Pressure on the sternal notch caused severe pain. Slight mobility could be obtained but the attempt was abandoned because of the distress caused. The second ribs went with the gladiolus and were not fractured. The sternal end of the left clavicle was slightly luxated but could be replaced easily, causing severe pain. The patient complained of acute pain on coughing or deep breathing. He had spat up small amounts of blood on six occasions. There was a

sharp stabbing pain which ran backwards from the right side of the sternum at the site of the dislocation to the right scapula. For a couple of days the patient was very distressed and unable to bend or to sleep. He was strapped in various ways which gave much relief and reduced the depth of the depression by about half an inch. Two months after the injury there were a depression of about half an inch, slight mobility, tenderness, and a friction rub on the left side of the ridge. Three months after the injury the patient could do only light work and was easily fatigued. Many cases of this dislocation have been described as fractures, but there is an amphiarthrodial joint between the manubrium and the gladiolus lined with hyaline cartilage and the bones are separated by a disc of fibro cartilage. Normally there is slight mobility of this joint. Cases in which this dislocation occurs are usually fatal from internal injuries. It is noteworthy that in this case the patient could walk within an hour of the injury and was treated throughout as an out-patient.

GONORRHOEA IN AN INFANT AGED TEN MONTHS; GONOCOCCIC INFLAMMATION OF THE SCALP.

THOUGH gonorrhœal vulvo-vaginitis in young children is far from rare gonorrhœal urethritis is extremely rare. At the meeting of the Société de Pédiatrie of Paris on May 15th M. Apert and M. Froget reported the case of a male infant, aged ten months, who was suffering from urethritis which was accompanied by a large phlegmonous swelling of the whole of the posterior hemisphere of the cranium. After 48 hours the redness and induration were limited to peripheral patches resembling those of erythema nodosum, while at the centre of the swelling was a white and soft œdema which quickly disappeared. In the meantime two small papules formed on one of the patches and became transformed into pustules. The pus which they contained showed polynuclear cells and masses of gonococci, as did also the discharge from the urethra. The origin of the gonorrhœa could not be ascertained. Inflammation of the scalp is a very rare complication of gonorrhœa. The rapid and almost complete resolution of the inflammation of the cellular tissue is noteworthy and the condition is analogous to the gonococci peritonitis of little girls, the onset of which is marked by great acuteness and is rapidly followed by complete resolution. Though the gonococcus is very tenacious on mucous surfaces its vitality in the cellular tissue is brief.

TOBACCO SMOKING BY THE IMMATURE.

WE hold no brief for the cigarette, nor do we fail to recognise the fact that smoking by juveniles is an evil, but the case for remedying the evil is not helped by doubtful statements. Everybody knows that tobacco is a poison and the suggestions, therefore, that tobacco is injurious because of its impurity or adulteration or because poisons are added to it are altogether beside the issue. If the tobacco smoked were the purest possible leaf the evil of smoking by juveniles, in our opinion, would be not a whit the less. If it were otherwise there would be no necessity for suppressing such smoking so long as the youth was supplied with pure tobacco. Since tobacco is itself a poison we need no further argument against indulgence in it by the immature or its abuse by the grown-up person. We can well believe that certain tobaccos are more poisonous than others but we very much doubt whether substances more injurious than tobacco itself are ever added to the manufactured leaf. Flavourings and sweetening substances, such as liquorice, glucose, and glycerine, are often added, but these are harmless compared with pure tobacco itself. Statements have been freely made that morphine or

even cocaine is added to cheap cigarettes in order to give them immediate soothing qualities or "to soften" the flavour of an otherwise harsh-smoking tobacco. We cannot accept such statements applied, at all events, to cigarettes retailed at five or even six a penny. The tobacco in such cigarettes is of an inferior and inexpensive kind we admit, but we have not been able to find the smallest trace of foreign poisons in some very cheap cigarettes which we purchased only recently and submitted to careful analysis. We doubt whether it would pay to add such comparatively expensive poisons. Opium is not cheap nor is cocaine. Tobacco of common quality is at any rate infinitely cheaper. The danger of smoking arises from tobacco poisoning and it is the wholesale and unchecked poisoning of the child with tobacco, chiefly in the form of cigarette smoking, against which the nation is asked to find a remedy. On what lines such a remedy can be made effectual we are not sure. It is obvious that different persons exhibit a different susceptibility to the poisonous action of tobacco even in the same country. In Oriental countries, however, excessive smoking, which is intensified by inhaling the smoke, commences almost from the cradle and is continued right through life apparently without any ill-effects.

Mr. Alderman Thomas Boor Crosby, M.D. St. And., F.R.C.S. Eng., L.S.A., has been elected one of the two Sheriffs of the City of London for the coming year. He has been for many years in practice in the City. Although there may be some doubt as to whether Mr. Alderman Crosby will actually be the first medical sheriff of the City of London, it is certain that for a great many years no medical practitioner has been elected to that ancient and honourable office, an office the serving of which is incumbent on every citizen before he can become Lord Mayor. We offer our congratulations to Mr. Alderman and Sheriff-elect Crosby and trust that before many years have elapsed we may be able to greet him as Lord Mayor of London.

THE King has given the undermentioned gentlemen His Majesty's Royal licence and authority to accept and wear the following foreign Orders which have been conferred upon them by His Highness the Khedive of Egypt in recognition of valuable services rendered by them: Mr. William St. Clair Symmers, M.B., C.M. Aberd., formerly professor of pathology in the Egyptian School of Medicine, the Imperial Ottoman Orders of the Medjidieh of the Third Class and of the Osmanieh of the Fourth Class; and Mr. Harold Nolan, M.D. Lond., medico-legal expert to the Egyptian native tribunals, the Imperial Ottoman Order of the Medjidieh of the Third Class.

THE annual distribution of prizes to the students of St. Mary's Hospital Medical School will take place on Monday, July 16th, at 4 P.M. They will be presented by the Director-General of the Army Medical Service, Surgeon-General Sir Alfred Keogh, M.D., K.C.B., who will afterwards unveil the memorial bronze erected in the entrance hall of the Clarence Wing to the memory of members of the Hospital and Medical School who lost their lives during the South African war.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ELECTION OF MEMBERS OF THE COUNCIL.

ON July 5th the election of three members of the Council took place. There were five candidates. Two of the retiring candidates offered themselves for re-election—

namely, Mr. Henry Morris and Mr. Richardson Cross—and there were three new candidates—Mr. G. A. Wright of Manchester, Mr. W. Bruce Clarke of St. Bartholomew's Hospital, and Mr. J. Charters Symonds of Guy's Hospital. The following was the result of the poll:—

	Votes.	Plumpers.
Mr. G. A. WRIGHT	462	46
Mr. HENRY MORRIS	386	21
Mr. F. RICHARDSON CROSS ...	340	10
Mr. J. CHARTERS SYMONDS ...	316	51
Mr. W. BRUCE CLARKE	305	48

749 Fellows voted by post and nine personally. There were two rejected voting papers; one was not correctly authenticated and the other contained votes for four of the candidates. One vote was received by telegram but it could not be admitted as it was unauthenticated. Mr. H. J. Price of Maldon and Mr. Willmott H. Evans acted as scrutineers. The President declared Mr. Morris and Mr. Cross re-elected and Mr. Wright elected members of the Council.

THE ANNUAL DINNER OF THE FELLOWS.

The third annual dinner of the Fellows of the Royal College of Surgeons of England was held on July 5th at the College in Lincoln's Inn-fields, after the election of members of the Council. The PRESIDENT, Mr. JOHN TWEEDY, was in the chair and about 70 Fellows were present. The President proposed the health of the King, the Senior Honorary Fellow, and then the health of the Queen and the Prince and Princess of Wales. He referred to the association of the Prince of Wales with the College in his position as President of the Imperial Cancer Research Fund. The President then proposed "The Fellowship of the Royal College of Surgeons of England." He said that he felt it almost necessary to apologise for appearing among them for the third time as President. On the first occasion on which the Fellows' dinner had been held at the College he had mentioned that it would be his last appearance there as President. He again declared that this was certainly his last appearance as President and on this occasion he was sure of what he said. The Fellowship of the College was a great institution; it was a symbol of the highest surgical attainments in the country and its diploma was sought after by the best surgeons in the colonies and in the United States of America. In these days of competition in degrees it was of interest to note that the Fellowship examination attracted yearly an increasing number of university students. The celebration of the centenary of the College in 1900 had led many to think that the College was only 100 years old, whereas they could trace back the corporate lineage of the College for nearly six centuries. In 1308 was to be found the first record or mention of the Barbers' Guild and at that time the barbers were engaged in the practice of at least some branches of surgery. From that time to the present there was an almost unbroken chain of descent and therefore it would be not unreasonable to celebrate in a year or two's time not the centenary but the sixth centenary of the origin of the College. One of the lectureships of the College, the Arris and Gale, dated from 1648. For a great part of the 600 years the surgeons were united to the barbers and it was not till 1745 that the separation finally took place. At one time the members of the College possessed the franchise for the City but when the separation finally occurred this privilege was lost. In proposing the toast of "The Fellowship" he coupled with it the names of Mr. W. Durnett Spanton of Hanley and Sir Edgcombe Venning.

Mr. SPANTON, in reply, suggested that in praising the Fellowship the Fellows were really praising themselves. Wherever one went one found the diploma of Fellow held in high esteem.

Sir EDGCOMBE VENNING also replied and proposed the health of the President.

The PRESIDENT, in returning thanks to the toast of his health, dwelt on the cordial relations which had always subsisted between his colleagues in the Council and himself. Differences of opinion there had been, of course, but such differences made for progress. Their convictions were strong but their personal relations were amicable. One object of the dinner was to allow the inspection of the additions to the Museum during the past year and therefore he would ask those present to inspect the specimens in the adjoining room.

THE
UNITED STATES DEPARTMENT OF AGRICULTURE
 AND
THE LANCET.

OFFICIAL REPORT ON THE CHICAGO STOCKYARDS IN ANSWER TO THE
 CRITICISMS OF THE LANCET.

REPLIES THERETO BY OUR SPECIAL SANITARY COMMISSIONER.

A PAMPHLET containing extracts from an official report on the Chicago Stockyards has been issued and we understand forwarded to all the members of the medical profession in this country. The pamphlet is entitled :—

COMMENTS ON "THE LANCET" ARTICLES AND
 "THE JUNGLE."

EXTRACT FROM REPORT OF THE COMMITTEE OF THE
 U.S. DEPARTMENT OF AGRICULTURE.

United States Department of Agriculture,
 Office of the Solicitor,
 Washington, D.C., April 13th, 1906.

This pamphlet is signed by JOHN R. MOHLER, Chief, Pathological Division, Bureau of Animal Industry; RICE P. STEDDOM, Chief, Inspection Division, Bureau of Animal Industry; GEO. P. McCABE, Solicitor, Department of Agriculture, committee. Approved and respectfully submitted to the Honourable Secretary of Agriculture, A. D. MELVIN, Chief, Bureau of Animal Industry.

By way of explanation the pamphlet opens in the following manner :—

"THE CHIEF OF THE BUREAU OF ANIMAL INDUSTRY, DEPARTMENT OF AGRICULTURE.

SIR,—In addition to the complete report, heretofore submitted, the committee appointed by you to examine and report upon the meat-inspection service of the Bureau of Animal Industry at Chicago, and the conditions of the abattoirs as to sanitation, has prepared a statement, giving the charges which have been published in various places from time to time reflecting upon the character of the work at that place, and submit comments based upon information gathered from personal observation."

Then follow 29 quotations from my articles on the stockyards and 11 from "The Jungle," together with comments thereon. All these quotations and comments in so far as they concern my reports are reproduced below; and, in each case, I have endeavoured to answer the comments.

Quotation from "The Lancet," Jan. 7th, 1905 :—

As for all the principles of sanitation laid down to govern the construction of abattoirs, these were ignored from first to last, consequently the insecurity is so great that several nations of the more civilised parts of the world have thought it necessary to enact special laws against Chicago.

Comment of the U.S. Department :—

The process of slaughtering cattle and packing the product is carried on in Chicago on a colossal scale, and it is

true in many instances, sanitary features, such as light and air, are sacrificed to increase the capacity of the plants. The reference to special legislation against Chicago by several foreign nations undoubtedly refers to the requirements of these nations that all pork from the United States shall be microscopically inspected for trichinæ.

"The Lancet's" reply to the comment :—

This comment practically admits the truth of my principal contention—namely, that though more animals are killed at the Chicago stockyards than in any other place in the world, there is no slaughter-house or abattoir in the technical sense of the term. The first rule governing abattoirs is the plentiful supply of air and light. These essentials, it is deliberately stated, are "in many instances" sacrificed. My next contention is that the care of public health must come first, but here we are officially informed that public health, as represented by the need of light and air, is "sacrificed" to Mammon "to increase the capacity of the plants"—in other words, the profits of the packers. This is a most barefaced admission of guilt. The reporters were well inspired when they used the word "sacrifice." It is indeed a sacrifice of every principle, of every sense of duty, that should be held most sacred. In many countries the law would severely punish persons capable of endangering the health of the community "to increase the capacity of their plants."

After such an admission, made in the very first comment, it is questionable whether it is worth while going any further. This might be considered enough in itself for the complete condemnation of the stockyards. What can be expected from people who sacrifice light and air for the sake of profits! After such a confession anything is possible. The faults that follow are the natural consequence of this fundamental lack of principle; they become, comparatively speaking, mere matters of detail. The following is the full list :—

Quotation from "The Lancet," Jan. 7th, 1905 :—

The importation of pork products from Chicago to Germany, Austria, France, and Denmark is prohibited unless accompanied by a certificate issued, not by any local authority but by the Government of the United States itself.

Comment of the U.S. Department :—

A microscopic examination of pork shipped from the

United States is required by Germany, France, Denmark, Italy, and Austria. This requirement applies not only to pork from Chicago but to all pork from any part of the United States.

"The Lancet's" reply to the comment :—

This confirms my statement and adds a nation to those which I had mentioned, namely, Italy, which when the list was given to me verbally at Chicago had been omitted.

Quotation from "The Lancet," Jan. 7th, 1905 :—

Therefore the cattle, hogs, and sheep, even at the Berlin rate for slaughter-house fees, would at Chicago bring in at least \$4,800,000 per annum. But a great amount of poultry is killed here, and there is also a very large horse market, so that the present amount of business done might easily bring in more than \$5,000,000, or £1,000,000 sterling per annum to the Chicago municipality.

Comment of the U.S. Department :—

The inference that horses are slaughtered for meat in Chicago is erroneous and without foundation in fact, so far as this committee is aware. The municipal ordinances of Chicago not only forbid this practice, but make it a misdemeanour to have horse-meat in one's possession.

"The Lancet's" reply to the comment :—

To say that I inferred that horses were slaughtered for meat makes me suspect that the writers of this report have never seen a genuine, that is, a properly built and organised, abattoir. If they had they would know that the slaughtering of horses is quite a separate industry, requiring, for instance, a totally different pavement. If there had been a horse slaughter-house at Chicago I should have looked upon it as another question. At Paris, for instance, there are the two slaughter-houses of La Villette and Vaugrard; but horses are taken to a third special establishment, some miles in another direction—namely, at Villejuif. In England this is considered so different a matter that we use a different expression, and while we take a bullock to the slaughter house we take a horse to the knackers' yard. All the cattle taken to the stockyards at Chicago are not slaughtered but many are exported alive and a large quantity go to England. So there is a cattle market and I was told that there was "also a very large horse market"—not a slaughter-house but a market—and had this been a municipal market the trade in horses would have contributed to the municipal receipts. This is all that I meant; this is all that I said; and to endeavour to make me say what I did not say seems to imply that there is not much fault to be found in the statement which I really made.

Quotation from "The Lancet," Jan. 14th, 1905 :—

The animals were killed, not in abattoirs, but in mills or factories—huge, hideous, box-shaped buildings, five and six storeys high. Private slaughter-houses were, and generally are, very defective when judged from the sanitary point of view; still they are preferable to slaughtering in factories. The number of animals killed is much smaller than in factories, and this is done not upstairs, but on the ground, and in a little building like a stable, where there is no difficulty in obtaining air and light. Nowhere could I discover the smallest trace of a slaughter house.

Comment of the U.S. Department :—

Accepting the author's definition of a slaughter-house, it may be stated that in Chicago abattoirs No. 94, No. 95, No. 96, and No. 198, all having Federal inspection, comply with these specifications. It should be stated further that

the sanitary condition of one of the above slaughter-houses was so poor that inspection has been withdrawn since the report of the committee was submitted

"The Lancet's" reply to the comment :—

There is a good deal of confusion here. It is impossible to compare the greatest slaughtering centre of the world with a private slaughter-house. As a rule, the latter would be taken to mean a small yard and shed behind a retail butcher's shop where one or two bullocks or half a dozen sheep are occasionally killed by the butcher and his assistants. These little establishments are often very defective. The object of establishing an abattoir or public slaughter-house is to do away with these defects, not to reproduce them, as, it is stated, was done at the Chicago abattoirs of which the numbers are given. But I did not see the places mentioned and am glad to hear that one of them, in any case, is to be shut up. This may be the thin end of the wedge and perhaps the places which I described as huge factories, where light and air are "sacrificed to increase the capacity of the plants," may also be closed, for presumably the withdrawal of inspection means the closing of the establishment. It would be more satisfactory, however if a positive statement were made to that effect.

Quotation from "The Lancet," Jan. 14th, 1905 :—

At the Chicago stockyards I could not but feel scandalised and humiliated when I saw the foul and abominable premises in which the representatives of science, the representatives of the United States of America, the representatives of the majesty of the law, condescended to work in the accomplishment of their mission.

Comment of the U.S. Department :—

The Federal inspectors in abattoirs are required to make a post-mortem examination of the animals at the time they are eviscerated and dressed. Under the most favourable conditions this work would not be considered by the majority of persons as being pleasant. There is, however, room for improvement in the facilities for the personal comfort of the inspectors at some of the plants.

"The Lancet's" reply to the comment :—

Here there is no attempt to disguise the fact that what I said was absolutely correct. When more is known concerning the management of model abattoirs it will be seen that the work can be made much more pleasant; that is, clean, free from bad odours, with bright healthy surroundings. But to those whose only experience is Chicago this would be beyond their powers of conception.

Quotation from "The Lancet," Jan. 14th, 1905 :—

As they (cattle) approach the outer wall, men strike them on the head with a mallet; then a sort of wooden partition gives way and lets the half-stunned animals fall into the basement of the building and beyond. As they come tumbling in, men seize their hind legs, affix ropes, &c.

Comment of the U.S. Department :—

The cattle are stunned in the knocking pens, after which a lever is pulled, causing the floor of the pen under the animal to tilt simultaneously with the lifting of the door. This permits the animal to roll out on the adjacent killing floor, a distance of about two feet below the level of the knocking pens. Should half-stunned animals fall any considerable distance, such as is inferred from the above paragraph, they would become so bruised as to lower their market value.

"The Lancet's" reply to the comment :—

Here is another attempt to make me say what I did not say. The idea that the animals might be bruised, that the packers would deliberately go out of the way to injure the quality of their meat, certainly never occurred to me. What I felt was that the process was dangerous and inhuman. Before cattle are struck a special headgear might be worn or the head should be roped down to such a position as would render it almost certain that the blow would be effective. In this case it often is not effective and I related that the animal on reaching the killing floor sometimes "jumps up and rushes about. It has then to be shot at the risk of the bullet striking an onlooker." It is this latter contingency which was the main purport of my complaint. But this part of my report is not quoted or denied. Further, in "The Jungle" it forms the turning point in the career of Mr. Upton Sinclair's hero, and the report of the Department of Agriculture seeks to refute this novel as well as my articles. The incident which I mentioned in a few bald words was subsequently described in the following graphic manner on p. 136 of "The Jungle." "A time of peril on the killing beds was when a steer broke loose. Sometimes in the haste of speeding-up they would dump one of the animals out on the floor before it was fully stunned and it would get upon its feet and run amuck. Then there would be a yell of warning—the men would drop everything and dash for the nearest pillar, slipping here and there on the floor, and tumbling over each other. This was bad enough in the summer when a man could see; in winter time it was enough to make your hair stand up, for the room would be so full of steam that you could not make anything out five feet in front of you. To be sure the steer was generally blind and frantic, and not specially bent on hurting anyone; but think of the chances of running upon a knife, while nearly every man had one in his hand! And then, to cap the climax, the floor boss would come rushing up with a rifle and begin blazing away. It was in one of these mêlées that Jurgis fell into his trap. That is the only word to describe it; it was so cruel and so utterly not to be foreseen. At first he hardly noticed it, it was such a slight accident—simply that in leaping out of the way he had turned his ankle." Thus rendered lame Jurgis loses his work and his downward career commences. The reporters of the Department of Agriculture have nothing to say to my few words and the graphic description of this brutal state of affairs as depicted in "The Jungle." The point to be answered is that we have here a method of slaughtering which involves cruelty to animals and peril to human beings. Instead of dealing with this, the real grievance raised both by Mr. Sinclair and myself, they start an imaginary point about bruises lowering the market value of meat. This, indeed, is typical of the psychology of all this special pleading. My plea for humanity, to man and beast, is met by the fear of lowering the market value of meat!

Quotation from "The Lancet," Jan. 14th, 1905 :—

Then, when strung up, the machinery carries the living animal forward and men have to run after it to cut its throat.

Comment of the U.S. Department :—

The stickers employed by the packing-house firms to bleed the cattle are active and adroit but the committee observed that it was unnecessary for these men "to run after" an animal in order to cut its throat.

"The Lancet's" reply to the comment :—

Here, again, while practically admitting that what I say is correct a straining effort is made to condemn my use of the word "run." Perhaps the word "hurry" or "hasten"

would have been more correct from the literal sense, though I think the word "run" conveys the truest impression. The "speeding of the pace" is so great that men are constantly running, though for distances of only three or four yards. However, if it can be of any solace to the Chicago packers and the United States Department of Agriculture I am quite willing to withdraw the word "run" and to put "hurry" in its place. But why waste time quibbling over such petty trifles when so many grave allegations of mine are passed in silence and remain unanswered?

Quotation from "The Lancet," Jan. 14th, 1905 :—

Sometimes the cattle are struck down and stunned more quickly than the men can pick them up and cut their throats, so they are left alive and some time suspended in the air by their hind feet.

Comment of the U.S. Department :—

The only cases where live animals were observed to be suspended in the air by their hind feet were animals to be killed by the Jewish method of shechtering. When an animal is struck down and stunned it is unconscious, practically dead, and it was noted that only a few seconds elapsed between the suspension of such an animal and the time it was bled.

"The Lancet's" reply to the comment :—

I do not understand the point of this comment unless it be to pretend that an animal when stunned is not alive. The cattle I saw were all hung up by their hind legs and suspended from a contrivance on wheels high up near the ceiling before their throats were cut. Delay occurs before they can all be hung up. As the animals sometimes spring to their feet and charge their butchers before they are tethered it is evident that occasionally they are inefficiently stunned. I maintain that the length of time which elapses between the stunning and the bleeding is an unnecessary prolongation of suffering. It is therefore cruel and there ought to be a law for the prevention of cruelty. Such a disgraceful manner of slaughter would never be tolerated in a model European abattoir. And this, which was my real point, remains unanswered.

Quotation from "The Lancet," Jan. 14th, 1905 :—

There are innumerable rafters, sharp angles, nooks, and corners where blood, the splashing of offal, and the sputum of tuberculous workers can accumulate for weeks, months, and years. It does not look as if the floors are ever really clean, though I am told they are occasionally scrubbed.

Comment of the U.S. Department :—

There are killing floors in Chicago which this quotation aptly describes without exaggeration. There are other killing floors which are kept as clean as the nature of the work will permit, with vitrified-brick floors, painted walls, and whitewashed posts and rafters. The floors of many of the killing departments and workrooms where meat is handled are scrubbed daily with caustic soda, pine tar, and boiling hot water, the floors then being dried with rubber squeegees and sprinkled with salt.

"The Lancet's" reply to the comment :—

Here what I said is admitted to be true and devoid of exaggeration. I visited the stockyards in November, 1904, and fancy that a great deal more hot water and caustic soda have been used after my visit than was the case before I wrote on the subject.

Quotation from "The Lancet," Jan. 14th, 1905 :—

Here is the evidence of the windows, about which there can be no doubt, and they are heavily caked with dirt.

Comment of the U.S. Department :—

The windows in some of the establishments are dirty ; in others clean. Some windows are caked with dirt on the inside, and others are only soiled on the outside by soot and dust.

"The Lancet's" reply to the comment :—

Again this is an acknowledgment of the correctness of what I said, though doubtless the present disclosures will have the good effect of causing the removal of the dirt denounced.

Quotation from "The Lancet," Jan. 14th, 1905 :—

It is safer to buy meat from the small retail municipal slaughter-house of a petty provincial town than from the world-wide provision packers of Chicago.

Comment of the U.S. Department :—

Government inspection is maintained at practically all of the abattoirs in Chicago and during a single year many thousand diseased carcasses are condemned as unfit for human food and are converted into grease and fertiliser, thus insuring their destruction. If these animals were slaughtered in abattoirs in small towns where no inspection exists they would undoubtedly be used for food.

"The Lancet's" reply to the comment :—

Naturally some inspection is better than no inspection, but however small the provincial town it is impossible to conceive a municipal slaughter-house without inspection. The first object in creating municipal slaughter-houses is to facilitate inspection.

Quotation from "The Lancet," Jan. 14th, 1905 :—

Close at hand there are closets, and they are in some places only a few feet from the food. These closets are at times out of order, deficient, defective, or even entirely devoid of flushing. They are all the more offensive as they are not sufficiently numerous for the large staff of workers who have to use them. This is especially the case in one of the rooms where soup is made for preserving in tins. In one department there were two closets, neither of which could be flushed, provided for 80 women, Even to-day, after many protests and agitations, there are no lavatories for the workers to wash themselves conveniently and to change some of their clothes before they begin handling the food which is sent from Chicago to all parts of the world.

Comment of the U.S. Department :—

It is true that in a small number of establishments water-closets are located only a few feet away from the food product, not even separated therefrom by complete partitions, and in a small percentage of the total number of closets examined by the committee the arrangements for flushing were defective, and in the same small percentage of cases the closets were not sufficiently numerous for the number of workers who use them. Generally speaking, however, the closets were ample in number and the facilities for flushing were all right, but sufficient care is not taken to keep them clean and the location of many of them is bad. The above comments apply to the criticism of lack of lavatory and dressing room facilities. Many of the establishments have large and commodious dressing rooms for both the male and female workers and lavatories are generally provided for the women but there are few lavatories for the men.

"The Lancet's" reply to the comment :—

More than a year must have elapsed between the publication of my complaints as to the condition of the closets and the visit of reporters on behalf of the Department of Agriculture and yet they found that some of the evils I described still existed. As these are matters that can be promptly and easily rectified, that such abominations should have been allowed to exist for more than a year after they had been publicly denounced shows how little the packers care for cleanliness.

Quotation from "The Lancet," Jan. 14th, 1905 :—

For instance, I was told that diseased and condemned carcasses which were put in at one end of the destructor to be converted into manure were promptly extracted at the other end and sold as meat.

Comment of the U.S. Department :—

For years rumours have been current that condemned carcasses, properly tanked, were reclaimed and sold for food. Careful precautions are taken to prevent this action. The condemned meat is required to be placed in the tanks in the presence of an inspector and the openings at both the top and bottom of the tank are sealed with Government seals and the steam turned on. The author himself in the same article says : "When a carcass, or a portion of a carcass, is condemned, in spite of stockyard gossip and scandal, I believe that it is conscientiously destroyed."

"The Lancet's" reply to the comment :—

There is now much reason to fear that if any part of my reports is incorrect it is precisely where for want of sufficient evidence I could not take upon myself to endorse the accusations, widely current, that diseased and condemned meat was not destroyed but sold for food.

Quotation from "The Lancet," Jan. 14th, 1905 :—

So that when stories go round about the selling of diseased meat the persons who tell them are either deliberately inventing or, more probably, confusing an ordinary cauldron with the destroying tanks.

Comment of the U.S. Department :—

This statement is believed to be correct.

"The Lancet's" reply to the comment :—

There is something singular about the guarded vagueness and brevity of this comment.

Quotation from "The Lancet," Jan. 14th, 1905 :—

Also I was told that bruised and rejected hams were nevertheless sold and put on the market by cheap butchers, or else the bone may be cut out and the discoloured portion of the flesh near the bone removed, the rest being utilised ; again, when meat that has been put in brine for pickling is found to smell, hollow needles are driven into the flesh, and brine is pumped into the body of the meat. This saves the time of penetration, and men have assured me that when meat still retained an unpleasant odour the operation was repeated. Nevertheless, I find some difficulty in believing these stories.

Comment of the U.S. Department :—

Hams rejected by the Federal inspectors are not permitted to be sold. Hams of healthy animals which are slightly bruised may be trimmed and the normal portion used for food. It is the custom to inject the pickling or curing

solution into hams, shoulders, and other thick portions of meat to hasten the process of curing. The committee was informed that sour hams were classed as such and sold at a reduced price. The committee took several samples of the pickle used in these needles and an analysis by the Bureau of Chemistry showed that the pickle contained a trace of borax, probably from the salt, and large amount of nitrates, but no sulphuric acid or sulphites.

"The Lancet's" reply to the comment :—

On the whole question of the sale for food of condemned and diseased carcasses I might have written differently had I read in those days the evidence given by President Roosevelt concerning the canned beef from Chicago which the soldiers under his command had to eat during the war in Cuba. Nor had I then any knowledge of the affidavit of Mr. Thomas F. Dolan who held a high position and was employed for ten years in the stockyards. He swore that the beef cast into the destructors was extracted at the other end and brought back into the dressing-room; that he marked some of the carcasses with his knife to recognise them; and that the workman named Nicholas Newson was especially employed to rescue the condemned meat from the destroyers or rendering tanks so that it might not be lost. Still, this is a phase of the question on which the evidence of my own eyes was of no avail. It has been more fully developed by Mr. Sinclair in his novel and needs more explanation that has as yet been produced by those who seek to defend the packers.

Quotation from "The Lancet," Jan. 14th, 1905 :—

They (condemned carcasses) are kept under the same roof on the same floor where food is being prepared for human consumption. Indeed, worse than this, the diseased carcasses are brought nearest to the windows so that there may be a better light to examine them. But, on the other hand, such air as may gain admittance into the huge building from these windows passes round, over, and between these diseased carcasses before it can reach the moist meat that is being cut up and prepared at a short distance.

Comment of the U.S. Department :—

In the case of hog carcasses which have been condemned for various diseases the final inspection is made on the hanging floor, usually near the windows, for the purpose of getting good light. This hanging floor is the room where the recently dressed carcasses are allowed to lose most of the animal heat before being placed in the coolers. No meat is cut up or prepared on the hanging floor. In all the abattoirs visited, with one exception, these condemned hogs are tanked directly from the hanging floor on the day of condemnation. In the case of condemned beef carcasses they are removed to the retention rooms, which are partitioned off from the coolers, sometimes by a solid partition, at other times by a slat partition, but always in such a manner that the air does not pass "round, over, and between these diseased carcasses" before it can reach healthy meat. No carcasses having putrefactive changes or unnatural odours are placed in these retention rooms. They are tanked at once.

"The Lancet's" reply to the comment :—

This, again, practically admits what I stated and the adding of further details does not alter my facts. It is admitted that meat which is going to be given out for food, since it is to be placed in the cooling-room, is on the same floor where diseased carcasses are hanging by the window. Therefore air entering by the windows does pass "round, over, and between these diseased carcasses" before it reaches the other and healthy carcasses that are about to be stored in the cooling-room previously to being sold for food. There is thus proximity between the wholesome and the unwholesome, whereas in all model abattoirs there is a quarantine

station absolutely distinct and removed from the slaughter-house, where everything that is at all suspicious is at once taken and isolated.

Quotation from "The Lancet," Jan. 14th, 1905 :—

When finally the carcass is taken to the destructor the opening of this tank—at least of the tank which I saw—is inside a large building in the floor, and round it many people were working. This place is dark, wet, and altogether in a most unsuitable condition for the handling of meat. Nevertheless, not only is human food prepared here but diseased carcasses, condemned as unfit for human food, are dragged through the compartment. The lid of the destructor is removed within a few feet of meat that is to be eaten. The promiscuity of the two occupations of examination and destruction of diseased carcasses and the preparing and cutting up or the washing of carcasses that are not diseased is most disgusting and reprehensible.

Comment of the U.S. Department :—

In some of the establishments the offal and fertiliser tanks are not sufficiently isolated. The committee saw no condemned carcasses being dragged through any part of a plant.

"The Lancet's" reply to the comment :—

Here again this abominable promiscuity between wholesome meat and condemned diseased carcasses is acknowledged to be a fact. Whatever the committee may have failed to see it is obvious that the diseased and condemned portions of meat had to be conveyed somehow or other to the fertiliser tanks which they admit are not sufficiently isolated.

Quotation from "The Lancet," Jan. 28th, 1905 :—

Then there is a department where a considerable number of women pack tongues in tins. Just behind them these tins are soldered and this operation produces a great heat. Also close at hand jets of steam are discharged into other tins so as to sterilise them. And yet not very far off there are cold storage rooms.

Comment of the U.S. Department :—

This description fits one canning room but is unfair as a generalisation. The room mentioned is in bad condition, much worse than the writer in the Lancet states. In this room water is dripping on the heads of the female workers who wear cloths on their heads to protect them from the drip. The air is surcharged with steam and solder fumes. Partitions and a power fan would do much to remedy the conditions in this room. In other canning departments the committee found good light and ventilation; power fans to take care of steam, and conditions made as sanitary, pleasant, and comfortable for the workers as was possible.

"The Lancet's" reply to the comment :—

What are we to think of the reforming capacities of the Chicago packers? Here is a room visited more than a year after I was there, and instead of being improved we are told that "the room mentioned is in bad condition, much worse than the writer in the Lancet states." After such an acknowledgment it will not be easy to accuse me of exaggeration.

Quotation from "The Lancet," Jan. 28th, 1905 :—

A partition would protect some of the women workers from the steam, but no one seems to care, and even so simple and inexpensive a device has not been adopted. Again, there is a blue paint employed to colour tins. Fine particles of this paint are blown about and have a distinctly irritating effect on the air passages, which predisposes them to more serious diseases.

Comment of the U.S. Department:—

In the larger canning departments the painting of cans is done with a machine, through which the cans pass, and the paint is sprayed on them. From one of these machines vapour was observed to rise; from the other machines no vapour was discernible.

"The Lancet's" reply to the comment:—

I do not remember seeing machines for painting cans. It is to be hoped that they are an improvement and that the inspectors will have the power to stop them if they cause injurious vapours.

Quotation from "The Lancet," Jan. 28th, 1905:—

This (spread of the bacilli of tuberculosis) is done by the boots of the persons going to and fro and by the pieces of meat which fall on the floor by the carcasses, notably of the big cattle, which are deliberately laid on the floor by the wheels of the trucks, &c.

Comment of the U.S. Department:—

It is conceded that if tubercle bacilli were present they could be spread by the boots of the workers, wheels of the trucks, &c., but the only place where the carcass is deliberately placed upon the floor is on the killing bed before the skin is removed. Facilities were observed for handling big as well as small carcasses and the inference that carcasses which are dressed are laid on the floor deliberately is incorrect.

"The Lancet's" reply to the comment:—

I did not say that carcasses were deliberately placed on all the floors but published the reproduction of a photograph showing a row of carcasses on a floor and said that pieces of meat fell on the floor. *Collier's Weekly* of April 22nd, 1905, contains some photographic reproductions of the interiors at the stockyards and one of them shows a large quantity of pieces of meat on the floor. Under the picture is the statement: "The meat on the tables and the floor is being prepared for market." Besides, in a comment on a quotation from "The Jungle" the reporters say: "The committee observed meat piled upon the floor in many places." I only said the meat fell on the floor, the commissioners say that it was *pi'd* on the floor, and yet they seem desirous of appearing to contradict me. One of the passages I wrote was worded as follows: "In these dark places the meat falls on the floor and comes in contact with the dirt from the boots of the workers and the bacilli from the sputum of a population among whom pulmonary tuberculosis is more prevalent than among any other section of the inhabitants of Chicago."

Quotation from "The Lancet," Jan. 28th, 1905:—

As already explained, anything like a thorough disinfection of the premises is impossible and is never attempted.

Comment of the U.S. Department:—

The visits of the committee to the various abattoirs were unannounced and unexpected, but it was a common occurrence to note that workmen were engaged in cleaning the floors, benches, and various portions of the machinery. In some houses the killing floors were washed with equal parts of caustic soda and pine tar, followed by an application of hot, steaming water. In other houses caustic soda and hot, steaming water only were used, while in still other cases the odour of chloride of lime was noticed in the cleaning mixture. In visiting cutting and trimming rooms it was frequently noted that the floors and benches were dry and clean, and that salt had been sprinkled about for the purpose of keeping these rooms sweet and clean and of preventing any odours in case a crack or crevice contained blood or scrapings that were not reached at the time the parts were washed. The usual method of cleaning was to apply washing soda and hot, steaming water, after which the floors were dried with rubber squeegees. A jet of hot,

steaming water had just been applied to the ferris-wheel scraper and accessories, sticking pens, and other portions of the killing floor of the house at the time of the committee's visit, and this observation was repeated at other times during the investigation. Nevertheless, this can not be considered as a thorough disinfection when the ceilings, rafters, &c., are not given similar treatment.

"The Lancet's" reply to the comment:—

No amount of washing will suffice. The floors and the walls to the height of about six feet must be watertight and the angles rounded off. Of course, there must be no rafters, and there must be plenty of air and light. In a word, the premises are utterly unfit for the purpose and should be vacated at once.

Quotation from "The Lancet," Jan. 28th, 1905:—

The smallest scratch or cut (on the person of the worker) will result in blood poisoning if the wound is not at once treated with a strong antiseptic. Then there are the festering sores of the men who work in the ham-curing department and who are constantly plunging their hands and arms in brine.

Comment by the U.S. Department:—

Many employees were interviewed with reference to the healing of small wounds on their bodies, particularly on the arms and hands. They stated that blood poisoning was not feared nor was it prevalent among them. In fact, they made light of the suggestion. Furthermore, the hands and arms of numerous employees who work in brine were noted, but no festering sores were seen in any case, but only the bleached, shrunken appearance of the skin, which is always associated with work in water.

"The Lancet's" reply to the comment:—

All I can say is that general medical practitioners living in the district spoke to me about the prevalence of such sores and blood poisoning. Nor does the above comment positively deny their existence but it is always difficult to get evidence from workers who fear that any indiscretion may cause them loss of their employment.

Quotation from "The Lancet," Jan. 28th, 1905:—

It may also be noted that the rendering vats are most dangerously placed. The lids are on the level of one floor, and the vat or tank is on the floor below. It is asserted that several persons have thus met with an awful death.

Comment of the U.S. Department:—

After careful inquiry the committee was able to hear of only one workman who had fallen into a rendering vat. The body of this man was immediately recovered and buried. This accident occurred several years ago.

"The Lancet's" reply to the comment:—

This is just one of those sensational things that deeply impress the public mind because of its dramatic terror. The presence of rafters in most of the buildings is far more dangerous but does not strike the public imagination. More lives are lost through bad sanitation than from accidents. I was anxious to avoid mere sensationalism; nevertheless, so many persons spoke about it, and it was so obvious that the vats were dangerously placed, that I should have failed in faithfully describing what I had heard and seen without some allusion to this dreadful rumour. The above comment goes much farther. It gives no mere record of the current gossip; it positively affirms that a man did lose his life by falling into the destructor or rendering vat.

Quotation from "The Lancet," Jan. 28th, 1905:—

Nevertheless, it will scarcely be credited, a large proportion of the stabling and cattle pens (in the Union Stock Yards) is on the bare earth. Here and there not to

prevent contamination but to secure a better roadway, a firmer foothold, and to reduce the mud nuisance, a sort of rough wood pavement was put in. This is made of the trunks of trees cut horizontally. These little round logs are placed side by side. This backwoodsman's expedient has now been replaced by the use of bricks, but neither bricks nor blocks prevent the contamination of the subsoil.

Comment of the U.S. Department:—

The Union Stock Yards at Chicago, Ill., contains 500 acres, about 50 of which are either covered by buildings or used for the storage of manure, lumber, &c. This latter portion, commonly known as "the dump," is the only area which is not paved or covered with flooring. Of the remaining 450 acres, an area comprising a very few acres, which includes the pens that are scarcely ever in use, is floored with planking and drained by box sewers. The remainder of the cattle pens, roadways, and alleys, comprising the vast area in daily use, is paved throughout with vitrified brick, having a low degree of water absorption. The moving of an office building permitted the committee to observe that the bricks adjacent to this structure were put down upon a substantial foundation. The drainage is good and the pens are kept as clean as the character of their use would permit.

"The Lancet's" reply to the comment:—

I have been informed that a great deal of pavement has been laid down since my visit to the stockyards. But surely the place where manure is stored should be rendered water-tight if the subsoil is to be saved from contamination. Then and in the name of the most elementary principles of sanitation, how can cattle pens be floored with planks and drained into box sewers? However, I hope that there has been considerable improvement of late in regard to paving.

Quotation from "The Lancet," Jan. 28th, 1905:—

It is over the bare earth also that the railway cattle vans, laden with livestock, arrive and discharge their freight. At Chicago the cattle step out on the bare earth, which they soil and contaminate.

Comment of the U.S. Department:—

The railway trucks and roadbed leading into the stockyards are similar to others throughout this country. The cattle are discharged from the cars on the wooden platforms and into the paved chute pens; then they are taken through overhead driveways to the different portions of the yards.

"The Lancet's" reply to the comment:—

I described what I saw and repeat that I hope some improvement has been effected since I was there. Still, those who are technically interested should compare the description of the railway arrangements given in this comment with my account of the railway station at the municipal slaughter-house of Berlin published in THE LANCET of July 14th, 1904 (p. 101).

Quotation from "The Lancet," Jan. 28th, 1905:—

Pending their sale, the animals have no suitable stabling provided for them.

Comment of the U. S. Department:—

These yards are, as a rule, not covered, although the cattle are usually removed from them for slaughter or shipment during the day on which they are received.

"The Lancet's" reply to the comment:—

Once again my contention is recognised as correct and obviously the cattle cannot always be so quickly removed.

Quotation from "The Lancet," Dec. 23rd, 1905:—

Protests have been made against the fact that the United States meat inspectors have to examine for trichinæ all the hog's flesh that is exported from Chicago to Austria, Germany, Denmark, and France, but that the hog's flesh exported to Great Britain or consumed in the United States is not so examined and guaranteed.

Comment of the U.S. Department:—

It is plain that this microscopic inspection is chiefly a

commercial matter, and that it was instituted for the purpose of regaining an export market for American pork products which had been excluded from certain European countries. Americans usually cook their pork before eating, and thereby render the trichinæ harmless. As a result the outbreaks of trichinosis in this country are very few and chiefly among foreigners. Thus, Dr. Ch. Wardell Stiles states that from the beginning of 1893 to Feb. 7th, 1898, there have been 40 or 50 cases of trichinosis reported in this country. ("Practice of Medicine," William Osler, 1898, p. 356.) Furthermore, funds are not available to extend this microscopic examination, for to carry out such an inspection of the carcasses of all hogs slaughtered in official abattoirs would require an appropriation of about \$4,110,000 for this purpose.

"The Lancet's" reply to the comment:—

This is another strange comment. Fancy struggling to prevent such a distressful disease as trichinosis chiefly for a commercial purpose. What has commerce to do with the question? It is a matter of humanity, not of commerce. It is a question of public health, not of European markets. As for expense, it is incurred in the poorest districts of Germany; surely the wealthy Americans, with their multi-millionaires, ought to be ashamed of alluding to money when there are human lives to be saved. At Berlin the microscopists get 55 pfennings per hog. Supposing double were paid at Chicago it would only amount to a quarter of a dollar, or a shilling per pig. The only argument on the question that can be held is an argument for or against the contention of the German men of science who maintain that the microscopic examination of pork for trichinæ is necessary. This is first of all a question of trichinæ and their likely effect. Expense and commercial interests must only be considered afterwards.

Quotation from "The Lancet," Dec. 23rd, 1905:—

It would seem as if the two city inspectors of meat, in their newly-awakened zeal, had shown more perspicacity than the Government inspectors, who are appointed by the central authorities of Washington and whose special mission it is to protect those foreign and European countries which have legislated against the importation of trichinæ from Chicago. In any case, the report says, speaking of the condemned meat: "Among these animals were six cattle that had been passed by the Government inspectors. Two cattle were found last week by the department inspectors that had been passed by the Government inspectors after the evidences of tuberculosis had been trimmed out. The city inspectors destroyed these cattle. The Government inspectors refused to allow the city meat inspectors to remove glands and other organs suspected of being diseased for the purpose of microscopic examination by the laboratory bacteriologists."

Comment of the U.S. Department:—

The visit of the committee to Chicago developed the fact that the Department of Health of the city of Chicago had no written or printed regulations governing the inspection of meat. In one case where ten carcasses which had been passed by Federal inspectors and then condemned by the city were re-examined by Drs. Mohler and Steddom and other veterinarians, it developed that the condemnation by the city was improper and the head of the city inspection force stated that these condemnations had been made by a city inspector, who at the time had his discharge in his pocket and was "anxious to get even."

It is true that the relations heretofore subsisting between the city inspectors and the Federal inspectors at Chicago have not been as close as is desirable. This defect has now been remedied, however, and the regulations of the Bureau of Animal Industry, governing the inspection of meat, have been adopted by the city of Chicago.

"The Lancet's" reply to the comment:—

This quotation is not taken from my four reports which were published in January, 1905, but from THE LANCET of Dec. 23rd, 1905. It opens out a three-cornered problem—namely, the responsibilities, first, of the Federal inspectors; secondly, of the old and obviously effete city of Chicago

inspectors; and thirdly, of the new and more efficient inspectors of the city of Chicago who began their work on August 7th. 1905. The latter decidedly accused the Federal inspectors of overlooking or allowing to pass carcasses which they should have condemned. Then the above comment shows that two of these Federal inspectors, Wohler and Steddum, have the same names, and these are not common names, as two of the three signatories of the report to the committee of the Department of Agriculture. If, as seems probable, they are the same persons, the question arises as to whether they are not too intimately and personally concerned in the matters at issue to be impartial reporters on the subject. In the last-mentioned and quoted article it is stated that in the week ending Sept. 23rd, 1905, 173,769 pounds of meat were condemned in the stockyards by the city inspectors, whereas during the corresponding week of the previous year only 2002 pounds of meat were condemned by the same authority. Other statistics are given to show that this disparity of figures is no exception applying to one particular week but is the general rule. Were the Federal inspectors Mohler and Steddum in office when only 2002 pounds were condemned in a week?

Quotation from "The Lancet," Dec. 23rd, 1905:—

It [slaughtering] is grossly inhuman, because no effort is made to mitigate the apprehension and torture of the animal.

Comment of the U.S. Department:—

The method of killing one steer with the percussion mask, recommended by this writer, requires more time than would be consumed in killing eight similar animals with a sledge hammer. And the inhumanity that has been charged against the latter method, owing to the very infrequent necessity of striking more than one blow, would be more than offset by the fright and the struggles of our range cattle caused by fastening the mask to their heads. It would be a diverting spectacle to witness the effort to affix the mask to the head of a wild, long-horn Texas steer, but the fear and apprehension of such an animal would be greatly enhanced.

"The Lancet's" reply to the comment:—

It was in a previous article that I spoke about using a percussion mask but I did not recommend this. My exact words were as follows: "When I inquired why a leather gear was not affixed to the bullock's head with a nail so placed in it that, however clumsy the stroke given, it would cause the nail to penetrate the brain and instantly kill the animal, I was told that such a process would take too much time." The fact was, I desired to ascertain what technical objections there might be to this mode of killing and quite understand that a tame stable cow and a wild long-horn Texas steer may require different treatment. But the method selected must be chosen for its humanity and not because it requires less time. The days are as long in Illinois as elsewhere and the time given in poorer countries can be even more easily afforded in wealthy Chicago.

After these 29 quotations from THE LANCET come 11 quotations from "The Jungle" which are likewise followed by comments. These latter Mr. Sinclair is well able to answer for himself. But there are some passages in the comments that bear on the question broached above. For instance, the reporters state that the Federal inspectors examine all carcasses "regardless of whether the meat is to be used locally, interstate, or for export." This I take it is a most alarming statement, because, as related in the last of my articles quoted, the Chicago city inspectors destroyed from August 7th to Dec. 1st, 1905, no less than 2,391,719 pounds of meat and fish and before August 7th only a trivial amount of meat was destroyed. But the Federal inspection was the

same before as after August 7th, consequently it cannot have been very efficacious. How this may be is, perhaps, indicated in another comment meant to refute Mr. Sinclair's assertion that from 400 to 500 cattle are turned into meat in an hour. The reporters say:—

"In the larger abattoirs in Chicago there are from 16 to 28 beds or divisions of the killing floor. A force of workmen in one of these abattoirs may kill and dress about seven runs of cattle in an hour, which means an average of from 110 to 200 beef carcasses per hour, but never from 400 to 500 such carcasses."

To this I would remark, first, that, if I understand correctly, it means that from 15 to 30 cattle are stunned and dropped simultaneously through the sliding door on to the killing floor. I get this number by dividing from 110 to 200 by the seven runs of cattle. If I am right, then this figure confirms my charge of cruelty; for a considerable time must elapse before all the 15 to 30 cattle can be picked off the floor, hung up by their hind legs, and begin to travel along by means of the contrivance on wheels to which they are suspended. It is only as they thus move forward with their heads hanging downwards that men strike at their throats with knives. Indeed, it seems as if this operation took the seventh part of an hour, so that a seventh part of an hour may elapse between the stunning and the bleeding.

Secondly, we have seen that one single killing floor out of the 16 to 28 killing floors may turn out more than a thousand carcasses in a day. All these inspectors must examine. According to the Prussian Minister of Agriculture, a veterinary surgeon should not have more than 20 animals to examine in one day. Does anyone imagine, for a moment, that there are enough Federal inspectors at the Chicago stockyards to do their work thoroughly? This explains why, when the meat to be consumed by the inhabitants of Chicago was properly inspected, the city of Chicago inspectors found that so large a quantity of unsound meat had been passed by the Federal inspectors.

Mr. Sinclair says that the people of Chicago "did not understand that these 163 inspectors had been appointed at the request of the packers, and that they were paid by the United States Government to certify that all the diseased meat was kept in the State."

This criticism applies to the pork which is kept for consumption in the United States and also in Great Britain, whether it has or has not trichinæ. But the other meat is supposed to be examined. The reporters in their comment in reply to the above passage say, "the meat sold to the people of Chicago, which comes from establishments having Federal inspection, receives precisely the same careful examination given to meat which is exported to Europe."

In my turn I object that when the town of Chicago really sought to protect itself the immense amount of meat which the Chicago city meat inspectors seized leads inevitably to the conclusion that the Federal inspection is very lax.

Much more might be said, but perhaps this is enough for the present. But why should officials and professionals, whose interests it is the object of THE LANCET to represent and to defend, appear before the public as if they held a brief on behalf of the Chicago packers? It is true that the reporters have very fairly and honourably acknowledged the accuracy of many things that I said, but they generally endeavour to follow such acknowledgment by some form of attenuation. They appear to be desirous of defending the packers rather than the cause of hygiene, which it is their business as health officials to endeavour to promote. This attitude I am at a loss to understand and it seems to be very unprofessional. When I wrote my reports on the Chicago stockyards I thought I was helping all the officials and all the inspectors to cope against abuses which it should be the purpose of their lives to remove.

ROYAL INSTITUTE OF PUBLIC HEALTH: ANNUAL CONGRESS.

THE annual Congress of the Royal Institute of Public Health, of which His Majesty the King is patron, was held in Queen's College, Cork, from June 27th to July 3rd.

Presidential Address.

The inaugural meeting was held in the large hall of Queen's College, where the President, Professor BERTRAM C. A. WINDLE, F.R.S., delivered his address. He said that if there was a country in the world which should be healthy, happy, and prosperous, filled with strong men and women, lusty children, and smiling homesteads, it was Ireland. In respect to health Ireland was, however, very far from being where it should be. Year by year the death-rate from tuberculosis was steadily declining in England and in Scotland and as steadily increasing in Ireland. Side by side with this advancing rate of mortality from tubercle there was an alarming increase in the number of the insane. Many attempts had been made to explain why Ireland should suffer so severely from these terrible scourges. Drink and bad housing might be factors in the cause but they did not explain everything. There was another factor which in England was not operative to anything like the same extent as it was in Ireland—namely, emigration—which year by year drained away the life-blood of the race in the shape of its youngest, its most promising, and its most valuable members. It has well been said that what was happening in Ireland was a survival of the unfittest and one might well ask what would be the fate of a stock farm where the best animals were sent away every year in large numbers and a large proportion of the comparatively unfit retained for the purpose of keeping up the breed. England perhaps owed Ireland a debt for industries destroyed in the past; but in this as in some other cases he thought it would be more profitable for the people to consider what they could do for themselves to ameliorate their position. He would like to ask the local authorities whether they were doing all that was in their power to stem the tide of disease? Were they taking all the advantages that they could from the Public Health Acts, from the Housing Acts, and from the other enactments? Were they making use of the provisions for the notification of disease and particularly of tuberculous disease from the ravages of which they were so severely suffering? Were they helping the medical profession in its struggle against the enemy by appointing bacteriologists in the towns and in the counties? Why, he asked, did Ireland wait for an excellent English society, like that which was paying it a visit, to take pity on the people of that country and stir them up to consider things which they ought to be considering for themselves? If the coming of the present Congress to Cork led Ireland to reflect on these things, and if, above all, it should lead to the formation of a society for Ireland, doing its useful work year by year in different parts of the island, then indeed they would have great reason to be grateful to the Royal Institute of Public Health for coming there.

SECTION OF PREVENTIVE MEDICINE.

Mr. DENIS DEMPSEY DONOVAN (superintendent medical officer of health of Cork), the president of the Section of Preventive Medicine, in his opening address referred to the geological position of Cork as well as to the meteorological conditions prevailing in that city. Referring to typhoid fever, he said that the most important point in the improvement of the health of the city during the past 25 years was the great diminution of that disease, due in a large measure to the action of the corporation which had carried out many important sanitary improvements.

Supervision of Milk-supplies.

Dr. E. W. HOPE (medical officer of health of Liverpool) read a paper on Directions of Possible Improvement in the General Supervision of the Milk-supply. He said that although admirable steps had been taken by the Local Government Board and the Board of Agriculture in this matter not one of them approached in importance the necessity of some central authoritative supervision of the milk-supply. Local authorities had power to make regulations for the control of cowsheds but in rural districts very

few steps had been taken to put these regulations into force. There should be inspection apart from local authorities. After some discussion Dr. Hope proposed the following motion which was adopted:—

That in the opinion of this meeting powers should be conferred on county councils and city councils to appoint inspectors to supervise the production and transport of milk and that great advantage would attend the appointment by the Local Government Board or the Board of Agriculture of a staff of medical or veterinary inspectors to coöperate with the officers and the authorities named.

In the course of the discussion Mr. DONOVAN said that a great deal of difficulty lay in the way of dispensary medical officers in Ireland doing their duty in this matter, as if they were to carry out their duties thoroughly they would frequently have to prosecute their masters and their patients.

Port Sanitary Administration.

Dr. J. WRIGHT MASON (medical officer of health of Hull) read a paper on this subject in which he advocated a more close and minute inspection of the food-supply and water-supply on board vessels. The powers at present invested in the Board of Trade for the inspection of food should, he said, be transferred to the port sanitary authorities. A motion was then carried to the effect that the clauses of the Public Health Acts or any other Acts relating to the inspection of foods should be extended to all port sanitary authorities.

Food Reform and the Prevention of Inebriety.

Arising out of a discussion on this subject a motion proposed by Miss MAY YATES (secretary of the Food Reform League) was adopted which stated—

That this Public Health Congress recommends that an educational food campaign be started to spread scientific information about this important subject.

Ignorance about food, Miss YATES contended, led directly and indirectly to infantile mortality and physical degeneration.

Cheap Sanatoriums.

After a discussion on this subject the following motions were adopted:—

1. That in the opinion of this Congress the time has come when the Government should encourage and contribute towards providing and maintaining a sanatorium for consumptives.
2. That it is desirable that every health authority should appoint a skilled bacteriologist whom any medical practitioner might consult in suspicious cases of consumption.

Prevention and Cure of Tuberculosis.

Professor E. J. MCWENEY contributed a paper giving an account of the defensive methods adopted in other countries against tuberculosis, its object being to enable the public health authorities in Ireland to submit for trial those methods which might seem most suitable to the conditions which prevailed in that country.

SECTION OF BACTERIOLOGY AND CHEMISTRY.

Dr. ARTHUR E. MOORE (lecturer on bacteriology in Queen's College, Cork), the President of this section, spoke of the necessity of adopting means whereby the sale of diseased meat should be made impossible. With regard to tuberculosis he said that sanatoriums afforded the only chance to those suffering from this disease short of emigration to another climate.

SECTION OF CHILD STUDY AND SCHOOL HYGIENE.

In this section Professor H. CORBY (Cork) read a paper entitled "Medical and Educational Aspects of our Schools—the Springs from which National Prosperity should Flow." The teacher, he said, should understand the elementary principles of sanitary science and strive to become an apostle and an evangelist of hygiene. School rooms were fruitful sources of illness, much of which could be avoided by the most ordinary precautions and, indeed, the health of the whole community largely depended on the regulations and sanitary condition of our schools. Damp, ill-lighted, and dirty schools were forcing-beds for consumption and other diseases and he thought it would well repay the Government or the local authorities to provide periodical medical inspection of schools. He hoped that no one would think he was unfairly criticising the Irish schools, for he considered the national schools of Ireland had been so far the salvation of the country.

At the annual meeting it was decided that the next Congress should be held in the Isle of Man.

Looking Back.

FROM

THE LANCET, SATURDAY, July 12th, 1838.

FACULTY OF LAUGHTER NOT PECULIAR TO MAN.

Of all animated beings, man alone, it is generally believed, is endowed with the faculty of laughter; it being the external and natural indication of mental emotions of which it is said animals are not susceptible. Hence Milton, in his *Paradise Lost* :—

“Smiles from reason flow,
To brute denied.”

The reverse of this opinion, however, is maintained on good authority. Le Cat affirms that he has seen the jocko both laugh and cry; * the orang-outang, exhibited some years since at Exeter Change, are said to have sometimes laughed when much pleased. But the last number of Brewster's *Philosophical Journal* contains the most conclusive evidence on this subject in a letter from Mr. Grant, giving an account of the structure, manners and habits, of an orang-outang from Borneo. The writer says, that if the animal be tickled, “the corners of his mouth draw up into a grin; he shows his teeth, the diaphragm is thrown into action, and reiterated grunting sounds, somewhat analogous to laughter, are emitted.”

In a note upon this subject it is stated by the original possessor of the animal, that with him and also with a young female, orang-outang, he has observed, when not excited by any apparent cause, a contraction of the upper lip, showing the teeth, and a play of the features resembling a smile, *as if excited by some pleasant idea*. The female, when tickled (withholding her breath and struggling) would utter a half-suppressed sound, (which might be expressed by the letters *Khr*.) much in the same way as some individuals of the human species when placed under similar circumstances.

NON-EXISTENCE OF EPIDEMIC DISEASES IN NEW SOUTH WALES.

We remember some years since reading an advertisement for medical practice, in which the advertiser wished for “a healthy situation :”—he would have been *transported* with the subjoined intelligence. “With the exception of catarrh, there are no epidemic diseases known; and those complaints which are common to children, in Britain, such as measles, hooping-cough, small-pox, &c. have no existence in this climate.”†

† Letter from New South Wales to Dr. Brewster, p. 119.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on June 28th, Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

Licences to practise physic were granted to Neil John McLean, University of Manitoba, and to Harry Francis Golding Noyes, University of Cambridge and the London Hospital.

The following communications were received: 1. From the secretary of the Royal College of Surgeons of England reporting proceedings of its Council on May 10th. 2. From the Anthropological Institute inviting the College to join a deputation to the Prime Minister to urge the institution of a National Anthropometric Survey. It was resolved that the invitation should be courteously declined, the views of the College having been sufficiently expressed in a report to the Privy Council two years ago. 3. From the General Medical Council forwarding a copy of a report from the Students' Practical Midwifery Committee with recommendations and inviting observations from the College. The consideration of the report was deferred until the next Comitia.

* *Traité de l'Existence du Fluide des Nerfs.*

A report was received from the representative of the College on the General Medical Council on the proceedings of the Council during its session in May last.

A report, dated April 23rd, was received from the Committee of Management and adopted. The report recommended—

1. That Dr. Theodore Dyke Acland be appointed the first assessor to the examinations of the Egyptian School of Medicine for the examinations to be held in December next.

2. That the course of laboratory instruction in public health given by Dr. William Hunter, Government bacteriologist, Hong-Kong, in the Government laboratory, be recognised as fulfilling the conditions of Clause 2, Paragraph II., Section II., of the regulations for the diploma in public health.

A second report from the same committee, dated June 11th, was received recommending that the Technical College, Sunderland, and the Municipal Day Technical School, West Bromwich, should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics. The recommendations were adopted.

A report from the Conjoint Finance Committee was received and adopted sanctioning the expenditure necessary for remedying grave defects in the drainage and sanitary appliances of the Examination Hall.

The PRESIDENT then dissolved the Comitia.

MEDICINE AND THE LAW.

Jury of Matrons.

RARELY of recent years has it been found necessary at the trial of a woman for murder to summon a jury of matrons, but such an event occurred at the last Bodmin Assizes when Carrie Thomes was convicted before the Lord Chief Justice of the crime of murder. When the ordinary jury of men returned into court with a verdict of “Guilty” the prisoner was called upon by the clerk of assize to plead in arrest of judgment and she pleaded in a clear voice that she was pregnant. The Lord Chief Justice said that this was not the proper time to urge that plea and proceeded to pass sentence of death. After sentence the prisoner by her counsel, as well as by herself, pleaded pregnancy and the judge thereupon ordered all doors to be shut and the sheriff to summon a jury of matrons *de circumstantibus*. This was done and the jury of matrons were sworn like a grand jury, the clerk of assize administering the oath in the following manner: “That you will diligently search and try Carrie Thomes, the prisoner at the bar, whether she be quick with child or not, and that your verdict shall be according to the best of your skill and knowledge.” The jury of matrons retired for half an hour and they returned a verdict that she was “quick with a living child.” The judge thereupon ordered that the sentence of execution should be respited until the child was born or until there was no possibility of a child being born. There are two cases, the one criminal and the other civil, in which the question whether a given woman is with child or not is submitted to the decision of a jury of matrons or other “discreet women.” In the first case the use of this means of inquiry is obligatory and by the court; in the second, optional and upon the petition of a private litigant. The procedure is of high antiquity and is stated by Blackstone to have prevailed in the pleas of the Crown “as early as the first memorials of our laws will reach.” In early ages, when medical knowledge was rare in amount and poor in quality, resort to a jury of matrons was, no doubt, the best and surest means of inquiry. Modern experience, however, does not justify the continued existence of a procedure which has often led to wrong results and for which the medical profession furnishes a more easily available, as well as a more trustworthy, substitute. The course usually followed is exemplified in Wycherley's case (8 Car. & P. 262). There Baron Gurney said: “Let all the doors be shut and no one be suffered to leave the court”—that is to say, to prevent the ladies present as sightseers from withdrawing and so declining an unwelcome office. At the trial of Catherine Webster, in 1879, the prisoner pleaded pregnancy, but unavailingly. The impanelling of a jury from among the lady sightseers on this occasion is said to have operated for a considerable time in diminishing the average attendance of lady spectators at the proceedings of the Old Bailey. The jury having been sworn withdraw with

the prisoner to make their examination. But they may desire, and will be accorded, the testimony of a qualified medical man, and probably in these days such testimony would in practice be considered indispensable. In Webster's case the verdict of the jury was given upon their own examination, and upon the evidence of Thyra Belsham, one of the wardresses of Newgate, and Mr. Bond, the surgeon who examined the prisoner. Were this not so, grave mistakes would occur, such as in the past have occurred, for "perhaps there is no subject on which average women display greater ignorance than on questions connected with pregnancy" (Tidy's Legal Medicine, Part II., p. 107). The books make mention of an early case where a mistake was made in this matter at Aylesbury (1 Hale, P.C. 369). And in modern times mistakes have been made, e.g., in the Norwich case (R. v. Wright (1832), *Medical Gazette*, Vol. XII., p. 22), in which a jury of matrons wrongly found a prisoner not with child. If medical evidence is called, the jury, it has been held, must return into court and hear such testimony given publicly on oath. In strictness the question to be decided is not whether the prisoner is or is not *priviment ensient* (i.e., barely with child: having conceived, "but not with quick child"), but whether or not she is *ensient de vivo enfant*; but in practice a jury of women will lean to mercy's side; for, says Lord Hale, "I have rarely found but the compassion of their sex is gentle to them in their verdict, if there be any colour to support a sparing verdict." In the Norwich case, however, a jury of matrons negatived the plea, though the woman was in the fifth month of her pregnancy. The reprieve is granted, not for the woman's own sake but *in favorem proliis*. And it holds good, at all events, until either the woman shall have been delivered or proved by the course of nature not to have been with child. The French law (Art. 127 of the Penal Code) is satisfied by medical evidence of pregnancy. In New York it is provided by statute that if there is reasonable ground to believe that a female defendant sentenced to death is pregnant a jury of six physicians shall be impanelled to inquire into the fact and if it is found by the inquisition that she is "quick with child" the execution is to be suspended until the governor issues a warrant directing it, which he may do as soon as he is satisfied that she is no longer "quick with child," or he may commute her punishment to imprisonment for life. In England the judges and lawyers who prepared the Draft Codes of the Criminal Code Bill Commission provided (Art. 531) for the abolition of the jury of matrons and the substitution in it for an examination of the prisoner by one or more registered medical practitioners.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County Borough of St. Helens.—Dr. John J. Buchan reports that considerable attention has been paid during the past year to the condition of the children attending the public elementary schools. Excluding the common zymotic diseases there were 625 cases under observation during 1905, and these comprised verminous conditions and sore heads, 137; ringworm, 29; itch, 6; eczema and other skin diseases and neglect, 238; sore eyes and ears, 72; non-notifiable infectious diseases (excluding measles), 116; and other causes, 27. These figures are sufficient to indicate what a very material benefit may accrue from a systematic attempt to obtain information with regard to the condition of school children and the resulting control cannot fail to exercise a good educational effect on parents and children alike. It may be hoped that supervision of this nature may result in greater cleanliness of the poorer classes and in an ultimate reduction of that great class of adults which may quite fairly be termed the offensively smelling class. If the education authorities can induce the children of this generation and, hence, the adults of the next to pay more attention to cleanliness and to take baths more frequently they will be doing an admirable service to public health and will be adding to the enjoyment of all classes, more especially in these days when class distinctions in the matter of travelling facilities, &c., are tending to disappear. As regards St. Helens, the council has decided to appoint a

hospital-trained nurse to visit any houses where there are children suffering from conditions which are largely the consequences of dirt and neglect and in the case of one of the two schools in the borough a short anthropometric survey of the children was made in the course of which height, weight, physical defects, eyesight, and general nutrition were gone into. It is satisfactory to note that the nuisance caused by the emission of black smoke in St. Helens is, according to the statistics, diminishing year by year, there having been in 1905 out of the 396 observations made 14.9 per cent. in which there was an emission of black smoke for a longer period than five minutes, the percentages in the immediately preceding years being in 1902, 28.5; in 1903, 22.1; and in 1904, 16.9.

County Borough of Sunderland.—The corporation of this borough subscribes for two beds in the Durham Sanatorium for Consumption and since 1901 50 patients from Sunderland have been under treatment at this institution. The results have so far been as follows: four still under treatment, 26 dead, 17 well, one ill, and two untraced. Of the 26 who died the average duration of life after discharge from the sanatorium was two years. Dr. Henry Renney advocates the exclusion of children from school until five years of age and the education committee has passed a resolution to the effect that "children under the age of five years be not admitted to the public elementary schools in the borough where such admission would have the result of bringing the average attendance above the authorised accommodation." The corporation has recently appointed a lady health visitor, the results appearing to be quite satisfactory, and the medical officer of health, in the interests of a reduction in the infantile mortality-rate, suggests that the health department should be informed of the birth of a child before the expiration of the six weeks laid down by statute. As he points out, during the interval many of the children born have died, and could the mothers be visited shortly after the birth of the child a considerable saving in infant life might be effected.

County Borough of Halifax.—Dr. J. T. Neech, dealing in his current annual report with the subject of small pox, furnishes an instance of a case where a group of six attacks of small-pox apparently arose from the arrival at the post-office of a letter from the small-pox hospital. No town in the kingdom has, Dr. Neech states, a purer water-supply than Halifax, the corporation having wisely purchased the gathering grounds connected with the storage reservoirs. The water of one of these reservoirs is liable to exhibit considerable acidity at certain times of the year, especially during February and March but by the addition of lime to the water as it leaves the main reservoir this acidity has been largely neutralised and there have been no cases of lead poisoning during 1905. Dr. Neech thinks, however, that a little more lime might be profitably added to the water.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8708 births and 3721 deaths were registered during the week ending July 7th. The annual rate of mortality in these towns, which had been equal to 13.2 and 12.4 per 1000 in the two preceding weeks, further declined last week to 12.3, and was lower than in any previous week of this year. During the 13 weeks of last quarter the death-rate in these towns averaged only 14.9 per 1000, and in London the rate in the same period was slightly lower—namely, 14.8. The lowest death-rates during last week in the 76 towns were 6.0 in Walthamstow, 7.0 in Leicester, 7.2 in East Ham, and 7.8 in Hastings; the rates in the other towns ranged upwards to 17.4 in Merthyr Tydfil, 19.1 in Rochdale, 19.6 in Wigan, and 20.2 in Wallasey. The 3721 deaths in the 76 towns showed a further decline of 43 from the low numbers returned in recent weeks, and included 406 which were referred to the principal epidemic diseases, against 380 and 372 in the two preceding weeks; of these, 122 resulted from measles, 92 from diarrhoea, 74 from whooping-cough, 46 from diphtheria, 45 from scarlet fever, 26 from "fever" (principally enteric), and one from small-pox. The deaths from these epidemic diseases were equal to an annual rate of 1.3 per 1000 in the 76 towns and to 1.4 in London. No death from any of these epidemic diseases was registered last week in Bolton, Croydon.

Plymouth, Northampton, Reading, or in ten other smaller towns, whereas they caused death-rates exceeding 3·0 per 1000 in Halifax, Salford, Coventry, Wallasey, Bootle, and Burnley. The highest death-rates from measles occurred in Wallasey, Manchester, Salford, Halifax, and Burnley; from diarrhoea in Devonport and Cardiff; and from whooping-cough in Coventry, Wallasey, Bootle, and West Bromwich. The 46 fatal cases of diphtheria included 12 in London, four in Manchester, three in Salford, three in Sheffield, and two in Newcastle-on-Tyne; and scarlet fever showed the largest proportional excess in Wallasey and Bristol. The 26 deaths from "fever" showed a further increase upon the low numbers in recent weeks, and included 12 in London, two in Portsmouth, and two in Preston. The fatal case of small-pox was recorded in Hull. The seven cases of small-pox under treatment in the Metropolitan Asylums hospitals at the end of last week showed a further decline from recent weekly numbers, and no new case was admitted during the week. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday, July 7th, was 2767, showing an increase of 15 upon the number at the end of the previous week; 376 new cases were admitted during the week, against 380 and 366 in the two preceding weeks. The deaths referred in London to pneumonia and other diseases of the respiratory organs, which had steadily declined in the 11 preceding weeks from 399 to 132, further fell last week to 118 and were 14 below the corrected average for the corresponding week in the four preceding years 1902-05. The causes of 39, or 1·1 per cent., of the deaths registered in the 76 towns during the week were not certified either by a registered medical practitioner or by a coroner. In London the cause of each of the 1113 deaths was duly certified, as was also the cause in 54 other smaller towns, including Leeds, Bristol, Bradford, and Newcastle-upon-Tyne. The proportion of uncertified deaths showed, however, a marked excess in Liverpool, Birmingham, Preston, Bury, South Shields, and Tynemouth.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 15·3, 16·0, and 14·5 per 1000 in the three preceding weeks, rose again to 15·3 in the week ending July 7th, and exceeded by 3·0 the exceptionally low rate in the 76 large English towns. The rates in the eight Scotch towns last week ranged from 10·6 and 11·0 in Perth and Aberdeen, to 16·7 in Glasgow and 18·0 in Dundee. The 524 deaths in the eight towns showed an increase of 27 upon the number returned in the previous week, and included 18 which were referred to diarrhoea, ten to measles, nine to "fever," eight to whooping-cough, four to diphtheria, one to scarlet fever, and not one to small-pox. In all, 50 deaths resulted from these principal epidemic diseases, showing a further decline of nine from the numbers returned in the two previous weeks; they were equal to an annual rate of 1·5 per 1000, which was 0·2 above the average rate during the week from the same diseases in the 76 English towns. The 18 deaths attributed to diarrhoea in the Scotch towns showed a further decline from recent weekly numbers and included eight in Glasgow, four in Dundee, and two in Paisley. Of the ten fatal cases of measles, also showing a decline from the numbers in recent weeks, five occurred in Glasgow and two in Edinburgh. The deaths from whooping-cough, which had been 15 and nine in the two previous weeks, further declined to eight, and included four in Glasgow and two in Aberdeen. All the nine deaths referred to "fever," of which six were certified as cerebro-spinal fever, were recorded in Glasgow, as were all the four fatal cases of diphtheria. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had declined in the four preceding weeks from 95 to 64, further fell last week to 52, and were 13 below the number returned in the corresponding week of last year. The causes of 18, or 3·4 per cent., of the deaths registered in the eight towns last week were not certified, the proportion of uncertified deaths in the 76 large English towns during the same week being only 1·1 per cent.

HEALTH OF DUBLIN.

The annual death-rate in Dublin, which had been equal to 20·2 and 16·4 per 1000 in the two preceding weeks, rose again to 16·9 in the week ending July 7th.

During the 13 weeks of last quarter the death-rate in the city averaged 21·4 per 1000, against 14·8 in London and 17·1 in Edinburgh. The 123 deaths of Dublin residents during last week showed an increase of four upon the low number in the previous week, and included four fatal cases of whooping-cough, whereas no death was referred to small-pox, measles, scarlet fever, diphtheria, "fever," or diarrhoea. Thus the four deaths resulting from the principal epidemic diseases were equal to an annual rate of but 0·6 per 1000, the rate from the same diseases last week being 1·4 in London and 0·5 in Edinburgh. The four fatal cases of whooping-cough showed an increase on the numbers returned in recent weeks. The 123 deaths from all causes in Dublin last week included 19 of infants under one year of age and 27 of persons aged upwards of 60 years. Five inquest cases and four deaths from violence were registered: 41, or 33 per cent., of the deaths in the city were recorded in public institutions, the proportion in London being 43 per cent. The causes of three, or 2·4 per cent., of the 123 deaths were not certified by a registered medical practitioner or by a coroner, the proportion of uncertified deaths in Edinburgh last week being 7·8 per cent., while in London all the causes of death were duly certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: J. W. Slaughter to the *Swiftsure* and J. Bradley to the *Royal Oak*. Staff Surgeon: E. A. Shaw to the *Hecla*. Surgeons: J. G. Wallis to the *Hecla*: M. W. Haydon to the *Swiftsure*; E. Cameron, P. F. Minett, and H. A. Browning to the *Vivid*, for disposal, to be lent to Plymouth Hospital; F. G. Goble and J. Bourdas to the *Pembroke*, for disposal, to be lent to Chatham Hospital.

ARMY MEDICAL STAFF.

Surgeon-General William H. McNamara, C.B., C.M.G., is placed on retired pay (dated June 29th, 1906); Colonel Francis W. Trevor, from the Royal Army Medical Corps, to be Surgeon-General, vice W. H. McNamara, C.B., C.M.G. (dated June 29th, 1906).

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel John G. Harwood to be Colonel, vice F. W. Trevor (dated June 29th, 1906); Lieutenant Alfred S. Millard resigns his commission (dated July 7th, 1906).

Lieutenant-Colonel William J. Macnamara, retires on retired pay (dated July 11th, 1906).

Captain R. E. G. Phillips is appointed for duty in the London district. Colonel G. W. Robinson has assumed the duties of Administrative Medical Officer, Colchester District, vice Surgeon-General W. B. Slaughter, A.M.S., who embarks for India. Lieutenant G. H. Rees is posted for duty at Portsmouth. Captain S. A. Archer will arrive for duty in Ireland at the end of July and is posted for duty in the Dublin District.

ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned Surgeon-Majors to be Surgeon-Lieutenant-Colonels (dated July 3rd, 1906):—William Nettle and James Turton.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the King's Own (Royal Lancaster Regiment): Arthur Henry Falkner to be Surgeon-Lieutenant (dated June 30th, 1906). 2nd Volunteer Battalion, The Royal Scots Fusiliers: Robert Nelson to be Surgeon-Lieutenant (dated June 30th, 1906).

EXAMINATION OF MAJORS IN THE ROYAL ARMY MEDICAL CORPS FOR PROMOTION.

The July Army Orders state that: "For 1907 the subjects for the examination of majors for promotion to lieutenant-colonel will be: Subject 3 (a)—The medical history of the more important campaigns and the lessons to be learnt therefrom:—The medical history of the Afghan campaign, with especial reference to the march from Cabul to Kandahar; and the medical history of the advance of Lord Roberts to Bloemfontein."

DEATHS IN THE SERVICES.

Surgeon-Major Hampden H. Maclean, A.M.D. (retired), on June 24th, at Northampton, aged 74 years. He joined the service in 1858, was promoted to surgeon-major in 1873, and retired in 1878.

Lieutenant Walter Hyde Hills, R.A.M.C., on June 23rd, at Cawnpore, India, aged 28 years. He entered the service as a lieutenant in July, 1904.

ARMY ADMINISTRATION.

At the moment of writing the air is full of unauthenticated rumours regarding the changes and economies about to be carried out in the army and political interest is, so to say, on the tiptoe of expectancy to learn what these are to be and what, in short, is to be our future army policy. The Secretary for War will be making his statement in the House just as we are going to press and consequently too late for us to notice whether any changes affecting the army medical services are announced. As it happens the unrest which has arisen in both North and South Africa at the present moment must be a source of some embarrassment to a statesman bent on carrying out any big and bold scheme of army economy.

STRIKE OF HOSPITAL STAFFS.

Under the above heading the correspondent of the *Standard* describes a remarkable state of affairs at Odessa. He writes that at noon yesterday (July 7th) "the whole attendant staff, numbering 760, including the cooks, of the city hospitals, declined to proceed with their work and abandoned 3000 patients. The strikers carried off the keys, stores, medicaments, &c., and fearing their violence the hospitals were surrounded by the military. The doctors and voluntary helpers in the hospital are praiseworthy doing their utmost to minimise the patients' sufferings. This strike is reprobed by the public."

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of this fund held on July 10th, Sir J. N. Dick, K.C.B., being in the chair, the sum of £55 was distributed among the several applicants.

Correspondence.

"Audi alteram partem."

STREET AMBULANCE SERVICE.

To the Editors of THE LANCET.

SIRS,—The decision arrived at within the last few days by a Parliamentary Committee to expunge the Ambulance Clauses of the L.C.C. General Powers Bill (1906) will doubtless have the effect of postponing any further action by the County Council for at least 12 months. It is now more than two years since a large proportion of the medical profession resident in London, which includes, as you state in your article last week, most of the leaders and heads of the profession, under the name of the Metropolitan Street Ambulance Association, urged upon our municipal authorities the pressing necessity for an ample and efficient ambulance service for its streets.

Nothing worth speaking of has yet been done to remedy this defect, though the matter has been repeatedly discussed by the London County Council, the Corporation of the City of London, the Metropolitan Asylums Board, and other public bodies. It would be very desirable to know upon what grounds the Committee of the House of Lords threw out the clauses in the Bill to which I have referred. It should be no secret, if progress is to be made, why Parliament refuses to permit the municipal authority of the metropolis to have the necessary enabling powers for dealing with that which for some time past has been, and still is, a grave reflection on the foresight and humanity of its citizens. In a matter of this kind time is pressing, the metropolis continues to grow, and additional factors are daily being included amongst those dangers of the streets of which the recent tramcar collision at Highgate is a disastrous example.

I am, Sirs, yours faithfully,

July 9th, 1906.

REGINALD HARRISON.

A LOCAL CENSUS.

To the Editors of THE LANCET.

SIRS,—In connexion with an annotation in THE LANCET of June 30th under the above heading it may be of interest to state that the corporation of this city carried out an unofficial census in 1897 and again this year; the reasons for

this were mainly that a sudden wave of prosperity in certain local trades had been accompanied by unwonted immigration and this had rendered the Registrar-General's estimate of the population unreliable. On both occasions the population was found to be underestimated. In the recent census the population was found to be 83,792, while the Registrar-General's estimate put it at 76,374. In the light of this information it has been possible to correct the estimated population for 1905; the correction shows that the death-rate was 13·7 instead of 14·8, the birth-rate 28·5 instead of 28·9, and the death-rate from seven infectious diseases 1·38 instead of 1·47.

The method adopted was the division of the city into 88 enumeration areas, each enumerator being furnished with a book; the particulars obtained were the numbers below three years of age, between three and five, between five and 14, and over 14, the number of rooms in each house, and the rent. The total expenses of the census amounted to £87 10s.

The fact of the census being taken on a certain day was extensively advertised and householders were informed that the information obtained would be regarded as confidential and would not be used against them in the event of overcrowding. In spite of this it is clear that such information being voluntary an unofficial census of this sort is liable to greater error than the official census and the error is probably in the direction of under-statement of the population. The great discrepancy shown between the figures obtained and the official estimate affords a very strong argument in favour of a quinquennial census.

I am, Sirs, yours faithfully,

E. H. SNELL,

Medical Officer of Health.

Coventry, July 10th, 1906.

THE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—In my reading of THE LANCET I find that you have very full and clear accounts of what is being done throughout the world in the prevention and treatment of tuberculosis, but apparently the work of the New York Post-Graduate Medical School in this direction has not as yet come under your notice. May I, therefore, present a few facts which perhaps will be of interest to your readers?

In the winter of 1897-98 Dr. John F. Russell of this city asked of the directors of the New York Post-Graduate Medical School that he might be allowed to put a few working people under treatment for tuberculosis in its dispensary. He wished to make an experiment to determine if proper care would cure tuberculosis in the early stages while the patients were still able to be about their daily work. The request was granted. It was arranged that the visits of the patients should be made in the early morning before work hours and in the evening after they had finished. No care of those who could not comply with the condition of two visits daily would be undertaken. In these morning visits the patients were made, in the presence of the nurses and attendants, to take the proper doses of mixed fats, an emulsion made by Dr. Russell, which contains 42 per cent. of fat, made of beef fat, coconut, peanut, and olive oil, equal parts, with about two drops of clove oil to each ounce of emulsion. It was also stipulated that the patients should be able to supply themselves with sufficient food of an ordinary quality at their home. There was no supervision of the food, clothes, and habits, except as to expectoration, sleeping in bad air, and so forth. No objection was made to any particular occupation. None but selected cases were accepted. Those having cavities were excluded and also all cases where a large amount of lung tissue was involved, even although there were no large cavities. Cases complicated with other diseases, such as bronchitis, emphysema, diseases of the kidneys, heart, and liver, were also excluded. And no patients were to be admitted whom the supervising committee appointed by the executive committee of the Post-Graduate Medical School and Hospital should regard as doubtful cases. They must be proved by the laboratory to be genuine cases of tuberculosis.

Matters have gone on very well in the dispensary. Although Dr. Russell has given up the care of it it is still maintained by the Post-Graduate School, and carried on by Dr. William Jay Mersereau, who has been for some time an assistant to Dr. Russell, one of the staff of the New York

Post-Graduate Medical School and Hospital. Ten reports were published, signed by the committee, stating the results of the treatment. Up to this point there have been 55 apparent cures in the dispensary in a space of about eight years. In addition to the work in the dispensary in 1905, through a gift of a sum sufficient to maintain a house called the Tuberculous Annex for two years, it has been carried on and in-patients to the number of eight may be, and are, treated in this place. The scope of Dr. Russell's work has been largely increased. In addition to eggs, milk, and Russell's emulsion, what is called vegetable food is given at the dispensary. This is prepared by taking equal parts by weight of raw vegetables, which after thorough washing by scrubbing with a brush and rinsing in fresh water (the skins are not removed) are mixed together and chopped in a chopping bowl until the particles are small enough to go easily into the receiver of the grinding machine where the mass is reduced to pulp. The pulp is collected as it falls from the machine and the juice squeezed out through coarse muslin cloth. To obtain the best results the machine should tear and grind rather than cut. Sausage or meat-chopping machines do not answer the purpose as well as peanut butter-making machines. In the latter machines two steel discs, ribbed, one of which revolves, face each other and are so arranged that the coarse vegetable material is fed in at the centre and after travelling the width of the plates escapes as pulp at the circumference. The hand machines are not expensive, can be adjusted to any table, and are easily kept clean.¹

The vegetables first used were potato, onion, beet, turnip, cabbage, and celery. Later, sweet potato, apple, pineapple, carrot, and parsnip; and still later, rhubarb (pie plant), summer squash, tomato, spinach, radishes, string beans, and green peas with the pods were added. The juice is prepared every day and kept on ice. In the treatment by over-feeding as practised by means of the emulsion and eggs it is found necessary to use cathartics quite regularly in order to counteract the effects of the large doses of fats. This vegetable juice has been found to be useful in two ways, to prevent inordinate doses of cathartics and also to assist the action of the fats, just as in what are assumed to be analogous conditions of scurvy patients are treated with acids and vegetables. Time enough has elapsed since the inauguration of the dispensary to say that a certain proportion of those under treatment are cured and this is also true of the more serious cases which are now treated in the annex.

This great problem of the cure of consumption cannot be solved in our country by sending patients to different air, to sanatoriums, for the simple reason the patients are not able to pay their expenses away from home. As the readers of THE LANCET very well know from the recent lectures by Professor Robert Koch, he affirms that the greatest difficulty in the way of stamping out tuberculosis is the want of money. The sum of money necessary to care for all the tuberculous patients in a hospital or even in dispensaries is so large that the end which the hospitals and dispensaries should finally reach will not be attained for many a long year on account of the want of money. There are not sanatoriums enough being everywhere provided for such patients, while there are many doubts if sanatoriums are the best places for working people, since it has been lately stated, if not shown, in this country that the cured working people come back flabby and really unable to work, so that the cure is only temporary and of no practical benefit. As is well known, there has come to be a wide difference of opinion in the profession as to how much is needed in the way of change of air for the cure of pulmonary phthisis. The patients coming to the dispensary are instructed by printed and verbal instructions, given them by a trained nurse, as to the conditions of living, necessity of avoiding spitting, and so forth, so that in their homes a great improvement is made in the prevention of new cases, but they live in ordinary tenement houses in a crowded city.

The experiments that have been conducted in the dispensary treatment of consumptive working people, without interruption to their work, are no longer doubtful ones. Every effort is being made to persuade the organised dispensaries in all cities and towns to treat self-supporting consumptive working people and influence the philanthropic to organise such dispensaries in sufficient numbers to

care for all wage-earners who are consumptive. The ordinary dispensary treatment in this country for patients with tuberculosis has been universally as follows. The patients are received, a diagnosis made, and if in teaching dispensaries and hospitals their cases are shown to the classes and instruction is given based upon them. They are given cod-liver oil, iron, and expectorants possibly in some cases. The dispensary hours are usually in the afternoon or at a late hour in the morning. If any of those coming to the dispensary are working people they must suffer an interruption or loss of a day quite often to carry on the treatment. As far as outsiders can see there is absolutely no hope in the minds of the physicians of curing these people, although the cod-liver oil assists in maintaining nutrition and in lengthening their lives.

The idea of the dispensary and annex connected with this institution is to demonstrate what now appears to be a fact, that patients may be cured under the conditions that have been indicated. It is certainly important that the work should go on until it can be settled beyond question whether or not it is worth while to treat consumptives in this way. A dispensary in imitation of that connected with the Post-Graduate Medical School has been founded for the treatment of tuberculosis in this country in Richmond, Virginia. The principles upon which this experimental dispensary and annex are maintained by the Post-Graduate School may be stated as follows: first, in the dispensary the patients must all be still able to earn their living; second, they must be able to sustain themselves with ordinary food; third, they must actually have tuberculosis, but no other grave constitutional disease; and, fourth, they must come regularly to the morning and evening clinics and while there take the nourishment given to them, in the presence of the nurses, in a leisurely way.

The treatment in the annex is while the patients are in bed and the temperature is usually maintained at that of the ordinary temperature outdoors, so that the patients are really living and sleeping in the open air.

I am, Sirs, yours faithfully,

D. B. ST. JOHN ROOSA, M.D., LL.D.

New York, June 23rd, 1906.

EPIDEMIC CATARRHAL JAUNDICE.

To the Editors of THE LANCET.

SIRS.—The term catarrhal jaundice is usually applied to that form of obstructive jaundice caused by catarrh, acute or chronic, of the bile-ducts sufficiently severe to cause obstruction, more or less complete, of the terminal portion of the common duct. Catarrh of the bile-ducts is stated to be due in most cases to an extension of catarrhal inflammation either from the gall-bladder on the one hand or the duodenum on the other; it is also associated with certain acute illnesses—e.g., pneumonia, influenza, the specific fevers, &c. In the series of cases recorded below these antecedent conditions were absent. The infectious nature of the disease is very clearly shown, although the exact method of infection and the nature of the contagion are obscure.

The fact that catarrhal jaundice sometimes occurs in epidemic form is noted by Osler in his "Text-book of Medicine" but the interesting point to determine is whether such epidemic catarrhal jaundice is a local manifestation of a general infection or whether it is essentially a local disease. The symptoms in each case were practically identical—viz., those of simple catarrhal jaundice. The patient complained of general malaise, headache, constipation, loss of appetite, and some nausea, with actual vomiting in two or three cases. About the third or fourth day the jaundice appeared with the conditions usually associated with it—viz., bile in the urine and clay-coloured stools. The temperature was invariably raised to some extent, varying from 100° to 101° F., falling gradually in three or four days to normal. The jaundice cleared up rather more rapidly than is usual and the patient was quite well and free from all symptoms and signs of the illness within three weeks of the onset in each case. The following brief notes of each case give the history of the epidemic.

CASE 1.—A lad, aged 18 years, was not under my care but I was informed by his employer that he had a mild attack of jaundice during the second week of September, 1905.

CASE 2.—A lad, aged 18 years, living in the house where Case 1 was employed; the illness began on Sept. 18th and ran the typical course described above.

¹ A good machine for the purpose is called the Quaker City Mill, f. 4, and is made in Philadelphia.

CASE 3.—A boy, aged 16 years, brother of Case 2 and living in the same house; the illness began on Oct. 4th.

CASE 4.—A young man, aged 23 years, brother of Cases 2 and 3, but resident at a farm about three miles away; the illness began on Oct. 9th.

CASE 5.—A young man, aged 25 years, brother-in-law of Cases 2, 3, and 4, resident at a farm about two miles from Cases 2 and 3 and an equal distance from Case 4. Illness began on Oct. 24th.

CASE 6.—A girl, aged 20 years, sister of Cases 2, 3, and 4, and resident in the same house as Cases 2 and 3. The illness began on Nov. 1st. This case was complicated by the fact that the patient was convalescent from scarlet fever, the rash of which appeared on Oct. 9th. It seems unlikely, however, that the jaundice was due to the specific fever, as it did not appear until three weeks after the onset of that illness. It is worthy of note that the somewhat rare symptom of xanthopsia, or yellow vision, was present in this case.

The following cases were not connected with those recorded above but illustrate the point of the infectious nature of the disease.

CASE 7.—A girl, aged 15 years; illness began on July 11th, 1905.

CASE 8.—A lad, aged 17 years, brother of Case 7, but resident at a farm two miles away; illness began on Oct. 27th.

In the first six cases it will be noticed that four occurred in persons living or employed in the same house, while the others, though resident several miles from the house and from each other, were relatives, and visited the house from time to time.

I had several other cases of simple catarrhal jaundice in the district at intervals during the six months from July, 1905, to January, 1906, but I could trace no connexion between them or the series recorded above.

I am, Sirs, yours faithfully,

T. EDWARD SANDALL, B.A., M.B., B.C. Cantab.,
M.R.C.S Eng., L.R.O.P.Lond.,
Medical Officer of Health of Alford.

acid coefficients. As the list was handed to me as one which is given to the public you can imagine my perplexity.

I am, Sirs, yours faithfully,

FREDK. WM. ALEXANDER,
Medical Officer of Health.

Public Health Offices, Bow-road, E., June 20th, 1906.

THE LIST OF DISINFECTANTS.

Bacteriological Test.

Method.—To five cubic centimetres of a particular dilution of the disinfectant in sterilised water add five drops of a 24 hours' blood heat culture of the organism in broth; shake and take subcultures every two and a half minutes up to 15. Incubate for at least 48 hours at 37° C. For further particulars see *Journal of the Royal Sanitary Institute*, vol. xxiv., part 3, p. 424.

STANDARDISATION OF DISINFECTANTS : PERPLEXITY.

To the Editors of THE LANCET.

SIRS,—As a public official advising a local authority upon health matters I am, indeed, somewhat perplexed respecting the best test to apply to find out the germicidal power of disinfectants. I have had placed in my hands a list of disinfectants with their carbolic acid coefficients quoted, at the foot of the list being the signature of a well-known author on the "Standardisation of Disinfectants." Among the various disinfectants is one which contains the disinfectant properties of chlorinated lime, the carbolic acid coefficient being stated as 21, and the test when applied to this chlorinated lime disinfectant, also with some other disinfectants, is stated to have been made in the presence of organic matter, the nature and quantity of such organic matter not being mentioned. I notice in the list that carbolic acid and other disinfectants have not been tested in the presence of organic matter, and yet the disinfectant with chlorinated lime properties and tested in the presence of organic matter (nature and quantity not stated) is compared with them. I also notice in the list that perchloride of mercury is stated to have a carbolic acid coefficient of 20, but the test has not been made in the presence of organic matter and this is compared to the disinfectant with chlorinated lime properties.

Now, Sirs, to increase my perplexity I find in a recent issue of a well-known weekly journal, no doubt read for the most part by municipal engineers, surveyors, and medical officers of health, all of whom have charge of the public health and have to advise their local authorities, that this same disinfectant with the properties of chlorinated lime has a carbolic acid coefficient of 21 and the test in this instance has been made by a physiologist and bacteriologist of great eminence. I am indeed perplexed, as I have always understood that tests for comparisons to obtain the carbolic acid coefficient are made with cultures in broth and sterilised water.

I inclose you the copy of the weekly journal in question and give below the list of disinfectants with their carbolic

THE TREATMENT OF CEREBRO-SPINAL MENINGITIS.

To the Editors of THE LANCET.

SIRS,—In the last nine weeks I have been brought in contact, directly or in consultation, with eight cases which I now believe to be cases of this disease. I had not seen a typical case since 1883 (in Vienna), but these cases have so closely resembled the pictures of the complaint lately drawn in many recent articles in the medical press (especially in THE LANCET of June 30th, p. 1815, by Dr. W. Wright and Dr. W. Archibald) that I cannot doubt their identity. There should now be no difficulty in recognising the condition even by a practitioner who has never seen a case of the complaint. But it is in regard to a logical treatment of the condition that I wish to draw attention. That the disease is specific goes without saying. The special micrococcus is recognisable and has been identified in numerous cases, usually by lumbar puncture. I wish, however, to question the special therapeutic value of this procedure. All the earlier clinical symptoms point to a localised infection of the upper spinal and basal meninges. Pressure from serous exudation explains all the symptoms present, including the auditory and ocular symptoms; all primarily irritative, and later parietic or paralytic, as the pressure increases. Relief of tension is, therefore, the first point of importance in treatment, and this I find is best obtained by the free use of leeches applied to the mastoid and posterior cervical regions repeatedly (a dozen or more at least) according to how much the symptoms may subside. This apparently resulted in early recovery in four cases.

But considering how many cases relapse and in how many local blood-letting is insufficient I wish to offer a suggestion for treatment more closely directed to the affected region than lumbar puncture (which appears to be the classical

method) and equally safe. I refer to cervical laminectomy. The fifth cervical lamina is easily accessible on either side, according to the lateral displacement, if cervical retraction be present, and should be exposed and turned upwards, leaving its upper periosteal attachment. After evacuation of the compressed serum a capillary drain should be introduced (of well-matured catgut which does not require subsequent removal) and an absorbent dressing applied. I do not think intra-meningeal irrigation with normal or antiseptic fluid necessary, as the fatal symptoms indicate mechanical pressure, not toxic poisoning, if one may judge by the temperature and pulse.

I have not yet had an opportunity of employing this method, but should feel safely justified in so doing in a suitable and necessary case. With a laminar bony valve over the aperture undue leakage is preventable by local pressure. The method presents little difficulty or danger and may be helpful where other means have failed. Medically, bromide of ammonium with small doses of iodide of potassium and chloral hydrate mitigate the irritative symptoms but leave tension unrelieved.—I am, Sirs, yours faithfully,

A. W. HARE, M.B. Edin.

Newquay, Cornwall, June 29th, 1906.

THE DIAGNOSIS OF TUMOUR OF THE UNCINATE REGION.

To the Editors of THE LANCET.

SIRS,—One of the cases recorded by Dr. Thomas Buzzard in his clinical lecture (published in THE LANCET of June 30th) is so like one seen by myself and the symptom-complex of these two cases is so rare and interesting that I venture briefly to describe my own for comparison. Dr. Buzzard's case was that of a man, 60 years of age, who had several seizures, in which he heard a sound like the clang of a piano, experienced a very disagreeable smell, and was obliged by a feeling of faintness to lie down. In the course of time left hemiplegia and left hemianopsia gradually developed. A diagnosis of tumour in the right temporoparietal lobe was verified by operation. In my patient, a man 62 years of age, the illness began with seizures in which he experienced a horrible odour which was attended with great dread and faintness or giddiness which obliged him to lie down, if he did not actually fall. These attacks of *petit mal*, as I called them, disappeared under bromide, but there gradually developed first right hemianopsia and then right hemiplegia, the patient dying within a few months of the first symptom. There was no auditory phenomenon in my patient, who, moreover, displayed quite early in his illness a symptom not present in Dr. Buzzard's case—i.e., word blindness—a difference clearly due to the fact that in his case the lesion was on the right, and in mine on the left, side of the brain. It was the presence of this word blindness plus the occurrence of attacks of *petit mal*, with such a definitely localising symptom as a special sense sensation, which made me from the first suspect the presence of tumour in the region of the left uncinatè gyrus—a diagnosis which was confirmed by the subsequent progress of the case.

I am, Sirs, yours faithfully.

Wimpole-street, W., July 7th, 1906.

HARRY CAMPBELL.

OSSIFICATION OF THE FONTANELLES.

To the Editors of THE LANCET.

SIRS,—I have been induced by reading Mr. T. Leahy Lynch's account of a case of ossification of the fontanelles and closure of the sutures of the skull at birth to record two cases which I had previously thought of reporting.

In August, 1904, I was called to examine a female child, seven days old, because of the peculiar shape of the head. I found the fontanelles completely ossified and the sutures closed. The parietal bones were united at an angle of about 150°, forming a distinct ridge along the vertex. The mother was a primipara and said that she had had severe labour pains for 25 hours before the child was born. There had presumably been dystocia due to the condition described, as at a subsequent confinement with as large a child the labour was a particularly easy one. The child thrived in a tolerably satisfactory manner but at times appeared to be drowsy and

irritable, when she would press her head against the mother. The latter thought the child suffered from headaches and I considered that she was probably right. The ridge has gradually become flattened and at present is hardly noticeable. Parentage: father, Dutch colonial, with probably a dash of coloured blood; mother, English colonial.

In October, 1904, I attended in her confinement at term a multipara. She was a woman with a roomy pelvis and on the os becoming fully dilated a male child was suddenly expelled with such force that he slipped through my hands. The head was small and of normal shape but the sutures and fontanelles were similarly closed. Within two days the child developed convulsions and subsequently vomiting and diarrhoea came on. These three symptoms continued at intervals until the child died when three weeks old. Parentage: father and mother both slightly coloured (Cape Dutch and Hottentot). In this connexion I might also record the case of a female child, aged five and a half months (father Norwegian, mother English colonial). On the third day of a very ordinary, almost afebrile, attack of diarrhoea she developed symptoms suggestive of cerebral compression and on examining the head I found the anterior fontanelle quite ossified. Death rapidly ensued and (although I do not profess that this is necessarily the correct scientific explanation) I attributed the phenomena to increase of the cerebro-spinal fluid, similar to the œdema one meets with in cases of infantile diarrhoea, the rigidity of the skull preventing any expansion.

I find no reference to complete ossification of the fontanelles at birth in Whittidge Williams's admirable work "Obstetrics." The cases recorded tend to show that congenital or premature ossification may prove also a factor in prognosis as regards the survival of the child.

I am, Sirs, yours faithfully.

GEORGE MARR, M.B., C.M. Aberd.

Kuysna, Cape Colony, June 9th, 1906.

SOUTH AFRICAN CIVIL SURGEONS.

To the Editors of THE LANCET.

SIRS,—Having received several inquiries concerning the South African Civil Surgeons' dinner we venture to ask for an opportunity of stating, through the medium of your columns, that no dinner will be held this year. It has been thought advisable in future not to hold the dinner annually as heretofore. The next dinner will be held in 1908 and in future the dinner will be held triennially. We hope that members will keep us informed of their addresses, as this will greatly facilitate communication in the future.

We are, Sirs, yours faithfully,

FRANCIS FREMANTLE } Hon. secretaries.
C. GORDON WATSON }

THE GERMAN PRACTITIONERS' ASSOCIATION.

(FROM OUR BERLIN CORRESPONDENT.)

THE German Practitioners' Association held its annual meeting this year at Halle, Professor LOEBKER of Bochum being in the chair. In his inaugural address the President alluded to the conflicts which had arisen between the sick clubs and the medical profession in certain towns. He said that the overwhelming power of the clubs made the coalition of the entire profession necessary and he was glad to be able to announce that in certain places—e.g., at Berlin—95 per cent. of the practising medical men, notwithstanding their differences in social, political, and other matters, had joined together in defence of their rights. The reform of the workmen's insurance law was in preparation and would soon be discussed in Parliament. Although workmen's insurance cannot be carried on without the collaboration of medical men, no representative of the medical profession had been invited by the Government to explain the wishes of the profession concerning the forthcoming Bill. The President further said that matters were very different in Austria, where the commission for the workmen's insurance law had included a number of medical men. Although the questions with which modern medicine had to deal in relation to problems involving public health and

¹ THE LANCET, May 19th, 1906, p. 1387.

other social matters necessitated knowledge which could only be supplied by experts, the Government had nevertheless refused to create professorships in "Social Medicine," and it is the merit of the Berlin branch of the Practitioners' Association to have opened, independently both of the Government and of the medical faculty, a seminary where both medical practitioners and medical students are instructed in the important matters with which "Social Medicine" deals. The President then pointed out that the lay public must be informed of the demands of the medical profession by the lay press and that for that purpose it was not unprofessional for a medical man to belong to the staff of a respectable lay journal. The President finally said that the profession in the struggles touching economical and social questions should never forget that their principal power was founded on medical science.

After the usual addresses of welcome of the representatives of the town, the university, and the other local authorities the meeting proceeded to discuss the forthcoming reform of the workmen's insurance laws. The sense of the meeting as expressed by different speakers was that the "free-choice" system should be made compulsory. It was further suggested that in the case of controversies between the clubs and the local profession impartial commissions, consisting of representatives both of the clubs and of the profession, under the presidency of a judge, should decide the matter, their verdict being final. Exception was taken to the fact that the law allowed people with a relatively large income to become members of the club and to enjoy all the benefits which were originally meant only for the indigent classes. The proposed amalgamation of the insurances against sickness, disablement, and accidents, which at present constitute three separate branches, was not considered to be in the interest of the medical profession. The meeting then adopted a motion that the reform of workmen's insurance must not be carried through without regard to the wishes of the medical profession. Other subjects discussed by the meeting concerned the so-called sick clubs for the middle classes not under the workmen's insurance laws. The association adopted a motion that it is unprofessional to act as a medical officer to these clubs at reduced fees. The third subject of discussion was the instruction of school children in hygiene. Professor HARTMANN, the chief medical officer of the Berlin municipal schools, read a paper on this question. He said that the propagation of hygienic knowledge was highly important and that this was best begun in childhood and by the school. The instruction in hygiene must be given by the medical officers of the schools in connexion with their regular visits. Also the school teachers should be directed to instruct the children whenever the occasion serves during a lesson; courses for the teachers should also be arranged. Another discussion dealt with locum-tenents and assistants. The Chemnitz branch proposed that medical students having passed the State examination should be allowed during a portion of the practical year required by the regulations to act as assistants to, or as locum-tenents of, medical practitioners instead of staying in a hospital. This motion was, however, rejected. In his closing address the President stated that the association had now 371 branches with 22,200 members and that 20,332 members were represented by 287 delegates at the present meeting.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE summer term has ended, the examinations are over, and at the Degree Convocation held on July 6th degrees were awarded in the midst of a brilliant assembly and much noise. It is difficult to understand why degree day should be looked upon as an occasion for the effervescence of animal spirits but so it has been and is. The Principal protested against the interruption but protest and argument will have little effect, except perhaps that of stimulation, and if the custom is to disappear it will die out gradually as it is doing in other places. If increase in the number of degrees awarded may be taken as an indication of the activity and prosperity of a university, then it will be granted that the University of Birmingham is in a very healthy state, for this year 83 degrees were awarded—that is

30 more than last year. After the degrees had been conferred a proposition was unanimously adopted offering the congratulations of all members of the University and its supporters to the Chancellor, the Right Hon. Joseph Chamberlain, M.P., on the seventieth anniversary of his birthday and tendering to him their thanks for the forethought and energy which he had exercised in accomplishing its foundation and for the care and advice which had guided its progress. In proposing the motion the Vice-Chancellor (Alderman C. G. Beale) made an excellent speech, reviewing in few words the main points of Mr. Chamberlain's work.

The New Maternity Home.

On Saturday, July 14th, the foundation stone of the new Central Home of the Birmingham Lying-in Charity will be laid. That it is badly needed will be readily understood when it is stated that there is not at present any institution of the kind where seriously dangerous maternity cases can be received for treatment. The practical work of the charity has hitherto been done by six certificated midwives under the direction of a lady superintendent, an obviously inadequate staff for so serious a purpose in so large a city. The new home is in Loveday-street, close to the General Hospital and St. Mary's churchyard. It is to be built of bricks and silver-grey terracotta on the pavilion system. It will consist of three blocks, will be provided with an isolation ward, will have beds for 16 patients, and accommodation for medical officer, nurses, midwives, and pupils. The buildings will cost £12,500, towards which £7,350 have already been received. A sum of £100 has also been promised conditionally on nine other donations of similar amount being collected and four of the nine have already been obtained. The building would have been erected at an earlier period but it was found that the site which was then available was not provided with sufficient light and air. Mr. Barrow Cadbury's generous gift of an additional piece of valuable ground not only disposed of this difficulty but it also enabled the governors of the charity to erect a better building with more extensive accommodation than was at first contemplated. In view of the importance and necessity of the work to be done it is to be hoped that the required funds will be soon obtained, not only for the new building but also for an increase of the general staff.

Boarding School for Feeble-minded Children.

On June 16th I drew attention to the attempt which the Rev. H. N. Burden was making to establish a boarding school for feeble-minded children. Mr. Burden believes that if the feeble-minded children are removed from the dangerous and vicious surroundings of the city and are properly trained they can be made into harmless individuals and in some cases they can be enabled to contribute largely to their own support. He is prepared to find the capital necessary to equip and to staff a proper building for the purpose, but before doing so he is anxious to obtain guarantees from public bodies that they will send him a certain number of cases to be paid for at the rate of £24 per head per year, that sum to include the cost of clothing. All the adjacent local authorities have been communicated with and the first replies from West Bromwich and Walsall were disappointing. Now, however, the Birmingham education committee has had the matter under consideration and has wisely decided to contribute to the support of not more than 20 cases. Mrs. Hume Pinsent, who presented the report of the special schools subcommittee, quite rightly pointed out that the public conscience has been aroused in connexion with this social evil and it is more than probable that future legislation will make the proper care and control of the feeble-minded compulsory. In any case Mr. Burden's attempt to provide a solution of the question deserves cordial support. It is an experiment, but an experiment directed thoughtfully and with good intent and nothing but good can result from it.

The Housing Problem.

By a vote of 30 to 16 the city council has approved the housing reform policy set out by the housing committee which stipulates that Birmingham should have statutory powers to plan undeveloped districts and to buy land without specifying the exact purpose for which it is purchased. This is a step in the right direction and it may now be considered probable that the parts of the city to be built will be arranged on some definite plan with regard to light and air space and that erectors of slum property will have to find some better occupation.

The Annual Report of the Medical Officer of Health.

Dr. J. Robertson's report on the health of the city during 1905 shows the lowest death-rate on record for Birmingham, 16.1 per 1000, a fall in the death-rates for zymotic diseases, typhoid fever, and pulmonary tuberculosis, and a reduction of the infantile mortality from 195 per 1000, at which it stood in the preceding year, to 155 per 1000 for 1905. It also notes a continued migration from the city to the suburbs and whilst this tends to vitiate the vital statistics of the city, still it must be held to be a healthy sign indicating higher ideals of comfort and surroundings. All this is very satisfactory but we must not forget to discount it by the fact that the climatic conditions of the year were remarkably healthy and by the further, and quite as important, fact that the birth-rate was only 29.2 per 1000, the lowest recorded for over 30 years. It is pleasant to note that medical men are loyally supporting the health committee's request for the notification of cases of pulmonary tuberculosis, for this is obviously an important preliminary step in association with the attack which must be made to keep that scourge in check. Dr. Robertson notes as a particularly important point in association with the public health the question of houses let as lodgings. Good sanitary provisions can be insisted upon in the cases of common lodging houses but the law is much less satisfactory as regards small houses which are taken and furnished by one person who lets off each room to a separate family, for the houses so let out are not in the least adapted to the purpose to which they are put, both water- and air-supply being often deficient. Clearly this is a subject which the housing committee might very well take in hand, for it is one which its proceedings with regard to the renovation of old property are likely to accentuate.

July 10th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

University of Liverpool: Medical Faculty.

The year 1905-06 has been one of marked increase in all the important divisions of the medical school of the University. The increase has taken place not only in post-graduate and research students, who have been steadily increasing in number from year to year, but also in the number of first-year students entering for the full curriculum. The number of first-year medical students who have entered for university degrees was 26, as against 13 in 1904-05, 17 in 1903-04, 19 in 1902-03, and 11 in 1901-02. The number of undergraduate students in the school during the present year is 139, as against 121 in 1904-05. The number of medical students is 31, as against 24 in 1904-05, showing a very desirable increase in this division. The number of public health students is 11, as against four in 1904-05. The number of students in tropical medicine who have entered in the three terms of 1905-06 reached 36, as against 23 in 1904-05. The number of research students remains practically constant, being 25 in 1905-06, as against 27 in 1904-05. The total number of post-graduate and research students in 1905-06 reached 63, as against 53 in 1904-05. The grand total of students in the school amounted to 217 in 1905-06 as against 197 in 1904-05. The standard of answers in the under-graduate examinations for the year has been good and the average of passes were high. At the examinations for the diploma of tropical medicine in July, 1905, three candidates presented themselves, of whom one passed and two were rejected. An improvement took place at the December examinations, when seven passed out of eight, whilst all seven candidates were successful in March, 1906. The amount of research work done in the school was evidenced by the fact that nine theses were submitted for the degree of Doctor of Medicine during the year, upon work done in different departments. Additions have been made to the departmental library and also to students' text-books of reference in the general library. The important collection of books known as the Thompson-Yates and Johnston laboratories departmental library has been arranged and carefully catalogued under the supervision of Professor R. W. Boyce, F.R.S. Dr. J. L. Todd, assistant lecturer in tropical medicine, has been appointed director of the Runcorn Research Laboratory. Dr. Todd returned from an expedition to the Congo Free State in September, 1905, and has since been engaged upon research work at the Runcorn laboratory in conjunction with Dr. A. Breinl.

Professor R. Ross, F.R.S., proceeded on May 20th to Greece in order to advise about malaria in that country, and returned on June 16th. During the year Professor F. T. Paul resigned the professorship of forensic medicine and toxicology, and in recognition of his distinguished services thereto has been appointed emeritus professor.

The Royal Infirmary and the Clinical School.

The Royal Infirmary has decided upon amalgamating with the United Hospitals Clinical School, so that one united clinical school will shortly take effect. Such an amalgamation is considered by the authorities of the University of Liverpool to make for the welfare of the medical school, and when it is accomplished Liverpool will be in the position of possessing one united school for clinical purposes, accessible to the student upon payment of one fee, thus affording the largest field for clinical work and clinical instruction in the United Kingdom. The advantages to the student of such an arrangement, especially in his fifth year of study after his clinical appointments have been completed, will be very great and the power of offering such advantages will undoubtedly give a great impetus to the Liverpool school. The medical board of the Royal Infirmary is to be congratulated upon having brought the negotiations to a successful issue, and in future it is to be hoped that a friendly rivalry between the constituents of one united clinical school may lead to development and progress in the matter of clinical teaching.

July 10th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

The Inspection of Meat in Bristol.

A REPORT which has recently been presented by the medical officer of health (Dr. D. S. Davies) to the health committee of the Bristol corporation, though satisfactory as regards the inspection of imported meat, has some disquieting features. There appear to be only two inspectors regularly employed for the inspection of meat. The city since the extension of its boundaries now covers 17,000 acres and has a population of 363,000 persons. There are 114 private slaughter-houses the inspection of which is practically left to one inspector, so that it is not surprising to learn that in Dr. Davies's estimation 100,000 carcasses escape inspection annually. In the same report Dr. Davies suggests that the newly appointed city bacteriologist should carry out an investigation for the purpose of ascertaining, among other things, whether there is evidence of certain organisms in canned meat from tins which are not blown but in which the meat is found to be non sterile. The city council will be well advised to accept this last recommendation of the medical officer of health.

Cardiff Infirmary.

The finance committee of the Cardiff corporation has decided to recommend the city council to subscribe to the funds of the infirmary the sum of 200 guineas, an amount equal to that subscribed last year. The corporation is at present not represented on the board of management of the infirmary and it is suggested that there should be a representation of five members.

The Medical Officer of Health of Pontardawe.

Since the passing of the Public Health Act, 1872, there have been two medical officers of health for the rural district of Pontardawe, near Swansea. Mr. Griffith Griffiths has been medical officer of health for many years of the western district but failed a few months since to secure re-election, for the apparent reason that a cow which had been sold by him and which was re-sold more than once was ultimately condemned as unfit for food. Owing to the reluctance of the rural district council to re-elect him the Local Government Board suggested that opportunity should be taken to appoint a medical officer of health for the whole district. After prolonged discussion the district council has not accepted the proposal of the Board but has re-elected Mr. Griffiths. However desirable it may be that there should not be more than one medical officer of health in each sanitary district, it can hardly be desirable to take advantage of such circumstances as those narrated above to make the change, involving as it would have done a censure upon the displaced official.

The Purification of the Avon at Bath.

The sanitary committee of the Somerset county council is bestirring itself in connexion with the purification of the river Avon. The sewage from the city of Bath is discharged untreated into the river and correspondence has taken place between the county council and the city authorities, the latter body inquiring whether the county council proposes to take up the question of the purification of the river along the whole of its course in Somersetshire. The corporation of Bath has not been inactive in this matter. Some ten years ago land was purchased four or five miles distant from the city at a cost of £10,000 and plans for a comprehensive sewage disposal scheme were prepared. The estimated cost of the scheme is over £100,000. One reason why more progress has not been made with it is the necessity for providing extensive main sewers throughout the city, the cost of which would be additional to that named for the outfall works. The Somerset county council is to be commended for the action which it is taking. This action would, however, be much more likely to be successful if the council had the advantage of the advice of a sanitary officer. Having definitely refused upon more than one occasion to appoint a medical officer of health the county council will be placed at a distinct disadvantage when conducting negotiations with sanitary authorities who can be advised, as in Bath for example, by a medical officer of health of experience.

The St. Columb Board of Guardians and its Public Vaccinators.

The question of vaccination expenditure has been for some time engaging the attention of the St. Columb (Cornwall) board of guardians and some short time ago, as a means of reducing the expense, it was decided to inform the five public vaccinators of the union that their fees would be reduced to the minimum charges allowed by the Local Government Board. Previously the fees had been slightly higher than in the majority of the other Cornish unions. At the meeting of the guardians held on July 6th it was reported that four of the public vaccinators accepted the reduction but one "absolutely refused" to do so. The guardians determined to give him immediately a month's notice to terminate his contract and to advertise the appointment.

District Medical Officers and the Supply of Medicines.

The Local Government Board for some years has been in favour of the guardians supplying their district medical officers with drugs for their parish patients and this procedure has been adopted by some unions in the West of England; the Bristol board of guardians, amongst others, provides its district medical officer with an excellent selection of drugs. The Tetbury (Gloucestershire) board of guardians at its meeting held on July 4th read a letter from the Local Government Board suggesting that it should in the future provide medicines for the district medical officer, but the guardians, after a considerable discussion, decided not to comply with the recommendation.

July 10th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Quatercentenary of George Buchanan.

THE University of St. Andrews commemorated on the Friday and Saturday of last week the 400th birthday of its most distinguished alumnus and principal, George Buchanan, and was "at home" on the occasion not only to the sister seats of learning in Scotland but also to those of England, Ireland, the colonies, the United States of America, and the European continent. The success of the commemoration was complete, from the fine choral service in the University chapel to Lord Reay's masterly discourse on the hero of the hour; from the banquet in the hall of the Students' Union to the garden party in the University demesne. The cosmopolitan character of the proceedings was in keeping with the genius of the man commemorated, the representatives of literature, science, fine art, and political affairs in the old world and the new combining to attest their admiration for the "humanist" who—not a decade too soon—caught up all that was most vital in the bequest of classical antiquity and prepared the post-renaissance world for its absorption and assimilation.

An "album," I believe, containing a full and officially revised report of the *oraisons de circonstance* will shortly be made public and will, I doubt not, prove a fitting memorial of one of Scotland's "forgotten worthies," whose fate it has been to receive more honour from the nations among whom he was a "stranger and a sojourner" than from that in which he was born and which rewarded his services with the scantiest of pittances in his life-time and with a pauper's funeral after his death.

A Convalescent Home for the Royal Edinburgh Hospital for Sick Children.

An appeal has been circulated by the directors of this hospital for a sum of £20,000 to enable them to establish a convalescent home in connexion with the hospital. The majority of children's hospitals have such homes in connexion with them and there can be no question as to the desirability of having them. By the beneficence of a lady a house at Muirfield, Gullane, has been bequeathed to the hospital and as the locality is most suitable the object of the directors is to alter and to enlarge the present building. The existing house is being used meanwhile for a few children, but the accommodation is very limited in view of the needs of the hospital. The scheme is deserving of support and it is hoped the directors will not appeal in vain to the philanthropic and the charitable who have money to bestow on such worthy objects.

The late Mr. Thomas Gilbert of the University of Edinburgh.

At the time of Mr. Gilbert's death reference was made in THE LANCET to the honourable position which he had held in the University. The *Senatus Academicus* at its last meeting put on record a long minute indicating its sense of its loss and that his "long and faithful services in divers capacities are worthy of most grateful commemoration." The minute concludes by stating that "all who have been brought into official contact with Mr. Gilbert have ever gratefully recognised his unflinching courtesy and his readiness to give them the benefit of his ripe experience. By many members of *Senatus* who knew him in his private capacity also his simplicity and uprightness of character, his genial kindness and humour, and his rare musical talent will long be remembered, and his loss will be mourned as that of a highly esteemed friend."

Notification of Measles and Pulmonary Tuberculosis in Edinburgh.

At a recent meeting of the public health committee of the Edinburgh town council it was decided by the casting vote of the chairman that it was desirable to have the first case of measles occurring in a family notified. It is some years now since the compulsory notification of measles was given up, partly on account of the expense. A further motion by Councillor Robertson, a medical member of the committee, as to whether the time had not come for the compulsory notification of pulmonary tuberculosis was referred to a subcommittee for report. It may be mentioned that the Midlothian county council has also had the notification of pulmonary tuberculosis before it quite recently and that it decided to do nothing in the meantime in view of the possibility of concerted action being taken. The matter seems to be somewhat maturing in this locality.

British University Students' Congress.

This Congress is to be held in Edinburgh, beginning on July 13th and going on to the 17th. On the evening of the 13th there is to be a dance in the University union. There is a varied programme of business, sight-seeing, and festivities.

Women Graduates and the University Franchise.

As was intimated in THE LANCET at the time the women graduates of the Universities of Edinburgh and St. Andrews took legal steps to have it decided whether they were entitled to vote at the election of the Member of Parliament for these Universities. The case has been before Lord Salvesen in the Court of Session and he has decided against the women graduates. No other decision was looked for and it may be hoped that the latter will not continue to throw away money in further testing the question in the law courts.

The Edinburgh City Hospital during 1905.

In the annual report of the medical officer of health the section dealing with the City Hospital contains a number of facts of much interest. This portion of the report is by Dr. Claude B. Ker, medical superintendent of

the hospital. During the year 2629 cases were admitted to the hospital. Of 230 individuals, including nurses and maids, exposed to infection only 11 nurses and three maids contracted the infectious diseases with which their duties brought them in contact. Taking some of the diseases dealt with reference may first be made to diphtheria; of this disease or suspected of having the disease there were 581 cases. In regard to the number it is remarked that cases are notified which ten years ago would not have been considered diphtheria. This is the result of bacteriological examination and the report thinks that the mere presence of diphtheria bacilli in the throat most doubtfully justifies a diagnosis of diphtheria. Of the 581 it was considered that 93 could not be said to be suffering from diphtheria. Of the 488 cases the mortality was slightly below 8 per cent. but the type throughout the year was mild. Post-diphtheritic paralysis only occurred in 42 cases—that is, 8·4 per cent. Of 67 cases in which the larynx was affected 15 died. Of 44 cases in which the nose was affected 15 died. The laryngeal cases were more severe than usual; of the 67 cases 34 required operation. The method of operation preferred is intubation followed by "secondary" tracheotomy if necessary. Of the 34 operated on 22 recovered and 12 died. With regard to antitoxin treatment, as a rule one dose was sufficient, but in severe cases doses of 8000 units were repeated two or three times. As regards the time of injection, of 20 cases injected the first day none died; of 141 injected within 48 hours 6, or 4·25 per cent., died; of 238 injected in the second 48 hours 20, or 8·42 per cent., died; and of 109 injected on or after the fifth day 13, or 11·92 per cent., died. Of the total 111 suffered from antitoxin rashes. Of 735 cases of measles 37, or 5·03 per cent., died and broncho-pneumonia was the main cause of death. Of 172 cases of whooping-cough 16, or 9·3 per cent., died; broncho-pneumonia following whooping-cough is treated in the open air. Of 740 cases of scarlet fever only 13, or 1·7 per cent., died. As regards complications 6·35 per cent. had nephritis, 11·50 per cent. otorrhoea, 11·50 per cent. rhinitis, 17·59 per cent. adenitis, and 4·46 per cent. arthritis.

The Preservation of Infant Life.

The Local Government Board of Scotland has just issued a circular to the clerks to local authorities suggesting that those authorities should make arrangements whereby public health departments, health visitors, district nurses, dispensaries, infants' milk depôts, and other organisations directly concerned with the problem of infantile mortality should be enabled to distribute a leaflet on the management of young children. The leaflet specially recommended by the Board for this purpose is entitled "Hints about the Management of Children," by the late Dr. James Barn Russell, for some time medical member of the Board and previously medical officer of health of Glasgow. The leaflet was prepared by him for the local authority of Glasgow and has been distributed by the registrars there for many years.

Epidemic Cerebro-spinal Meningitis in Glasgow.¹

Dr. A. K. Chalmers, the medical officer of health of Glasgow, states that since his memorandum of three weeks ago 13 other cases suspected of suffering from cerebro-spinal fever have been reported in Glasgow. Out of these cases in four instances at least the specific micro-organism of the disease was obtained. In one case the patient was aged three weeks, another was seven months old, four were under five years, five were under ten, one was under 15, and one was under 25. One of the cases, a baby seven months old, well illustrates the malignity with which the disease may occur, 12 hours only elapsing between invasion and death. Further evidence of the distribution of the disease is being afforded by the occurrence of two cases in Ayrshire; one of the patients, however, resided in Lanarkshire and is in business in Glasgow.

Ayrshire Sanatorium for Consumptives.

This sanatorium, erected on the banks of Afton water, was opened last week by the Countess of Eglinton. The movement for the building of a sanatorium for Ayrshire had its inception at a meeting of the directors of the Ayr County Hospital seven years ago. The directors saw that it was impossible to combat consumption with the means at their disposal in existing hospitals and, along with the directors of the Kilmarnock Infirmary, they

con- v- n- d a public meeting at which the preliminary steps were taken to erect this sanatorium. They had no difficulty in raising the money and the whole cost will be under the estimated sum of £10,000. The expenditure includes the purchase of 55 acres of ground, gas and water works, drainage, roads, paths, and fencing, as well as the buildings and furnishings. The accommodation is at present limited to 14 beds, but it is the purpose of the directors to increase this when it seems advisable. The site appears to fulfil every required condition. It has 800 feet of elevation with pure mountain air; it is not too near a town; it has good soil, a good water-supply, and plenty of walks at different gradients.

July 10th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Hospital for Incurables, Dublin.

THE annual meeting of the supporters of the Royal Hospital for Incurables, Donnybrook, Dublin, was held in the institution on July 5th, Mr. William Fry, chairman of the managing committee, presiding. There was a large attendance, which included the President of the Royal College of Physicians, Sir William J. Smyly, and Mr. H. R. Swanzy, President of the Royal College of Surgeons. The chairman said that the institution was founded so far back as 1743 and that it was non political and non sectarian. It contained 213 beds and at the present time held 211 patients, while it proved impossible to accommodate anything like the number of applicants for admission. At the last election there were only four beds vacant and 28 candidates.

Testimonial to the Rev. W. Delany.

On June 30th a meeting was held at the Shelbourne Hotel to inaugurate a scheme for commemorating the services to education of the Very Rev. William Delany, President of University College, Dublin, who had just attained the dignity of his golden jubilee. The Right Hon. C. Pales, LL.D., Lord Chief Baron of the Exchequer, presided and it was decided that the most suitable memorial would be an exhibition in University College, open to students of intermediate Jesuit colleges in Ireland.

Death of Dr. M. A. MacDonnell.

The lamented death of Dr. Mark Antony MacDonnell, who was formerly well known in Ireland, took place on July 9th at his residence, 14, Ridgeway place, Wimbledon. Dr. MacDonnell was formerly Member of Parliament for Queen's County, where he was elected as a Nationalist in 1892 and re-elected in 1896 and 1900. He graduated at Queen's College, Galway, in 1876, taking the degrees of M.D., M.Ch., and L.M., and subsequently practised in Liverpool where he was surgeon to the Liverpool Cancer and Skin Hospital and consulting officer to Toxteth Infirmary. He was born in 1854 and was a son of the late Mr. Mark Garvey MacDonnell and brother to the Right Hon. Sir Antony Patrick MacDonnell.

Overcrowding in Belfast Schools.

At a meeting of the Belfast board of guardians held on July 3rd the Local Government Board reported that its lady inspector, Mrs. Dickie, draws attention in her report to the fact that the condition as regards cleanliness and ventilation of the primary (National) schools is for the most part very unsatisfactory. The floors, she says, are seldom washed, the accommodation is frequently insufficient, and the arrangements for ventilation are generally defective. The boarding-out committee, in conveying the report to the Belfast guardians, states that it is in perfect agreement with the inspector's report as to the want of cleanliness, want of ventilation, and the overcrowding in almost all cases. It recommends that the extract in reference to the schools from the inspector's report should be given to the press and it advises that a representation should be made to the Board of Education *re* the dirty, insanitary, and overcrowded condition of the great majority of the schools in Belfast.

Portadown and Banbridge Water supply.

The new water-supply for Banbridge and Portadown, which comes from the Shinna river in the Mourne mountains, was turned on to supply these towns on July 5th. The works are estimated to cost about £70,000.

¹ See THE LANCET, June 30th, 1906, pp. 1815 and 1861, and July 7th, p. 47.

The Belfast Mater Infirmorum Hospital.

The Saturday collection on June 30th for the Mater Infirmorum Hospital, Belfast, amounted to the sum of £1025 15s 7d., which includes the district collections and £78 7s. 5d. handed in at the hospital.

The Medical Officer of Health of Belfast.

The Local Government Board (with which the veto rests) has written the Belfast City Council to the effect that it will approve of a salary of £800 or more per annum for the new medical officer of health of Belfast but that it cannot agree to a smaller amount. The council had proposed £600.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Etiology, Pathology, and Treatment of Aneurysms of the Great Vessels.

At a meeting of the Academy of Medicine held on June 26th M. Lancereaux read a paper on the etiology, pathology, and treatment of aneurysms of the great vessels. He said that such aneurysms, especially when affecting the aorta, were the usual effects of the action of the various microbes of three important diseases—namely, tuberculosis, syphilis, and malaria. In certain cases the organisms on which these diseases depended made their way into the outer coat of the arteries and brought about the formation of new elements of connective tissue; these caused thickening and sometimes penetrated in the form of cellular processes into the middle coat which they perforated. This diminished the resistance of the arterial wall, which, under the influence of the blood pressure, at last gave way, the result being either hæmorrhage or the formation of an aneurysmal sac. In these circumstances prophylactic treatment consisted in preventing the deterioration of the vessels. For this purpose mercurial preparations and iodides were indicated in cases of a syphilitic nature and in aortic scleroses of malarial origin, at least in the incipient stage. When an aneurysm had formed, the usual, and in fact the only satisfactory, treatment was the application of a ligature. This method, however, was dangerous when the artery was large and in the case of the aorta it was impossible, but in these circumstances attempts might be made to induce the coagulation of blood within the aneurysmal sac by the injection of gelatinised serum. The success obtained in this way by M. Paulesco and himself in a large number of cases left no room for doubt as to the efficacy of the method; with respect to its alleged dangers M. Lancereaux had no hesitation in saying that they were non-existent, provided that the fluids employed were perfectly sterilised, and this was proved by the fact that in nearly 1200 injections of gelatinised serum he has never had the slightest mishap.

Adhesive Pericolicitis.

At a meeting of the Surgical Society held on June 27th M. Sieur read a paper on adhesive pericolicitis occurring in a young soldier who had for several years suffered from pain in the right hypochondrium and severe constipation. Eventually he was suddenly seized with symptoms of intestinal obstruction. From the copious vomiting of bilious fluid, the flattening of the abdomen, the pain on pressure, and the dulness on percussion in the left hypochondrium it was inferred that the obstruction was situated in the last portion of the duodenum and laparotomy showed that the diagnosis was correct, for the duodeno jejunal angle was firmly compressed by pericolic inflammatory adhesions which seemed to envelop also the stomach and the liver. M. Sieur broke down the adhesions as carefully as possible and closed the abdomen after inserting a drainage-tube, as there was a prospect of perforation of the duodenum, its walls being in an unhealthy condition and apparently very friable. The further progress of the case justified this course, for several successive perforations of the duodenum occurred during the next few days and the patient died on the eighth day. The necropsy showed the existence of pericolic adhesions extending from the hepatic flexure of the large intestine and partially enveloping the liver, the stomach, and the spleen. The biliary passages were normal. On the other hand, the mucous lining of the large intestine was inflamed and in

several places it was ulcerated. In the last portion of the duodenum there were five perforations. M. Sieur was of opinion that the condition was adhesive peritonitis following chronic enteritis and causing obstruction by compression of the bowel at the junction of the duodenum and jejunum.

Mistletoe in the Treatment of Hæmoptysis.

At a recent meeting of the Therapeutical Society M. W. René Gaultier read a paper on the use of mistletoe as a remedy in hæmoptysis. Two cases of hæmoptysis had to his knowledge been successfully treated by the mistletoe of the oak given on the advice of a woman not possessed of any medical training and some foreign medical men had employed it long ago for the same purpose. M. Gaultier therefore tried an ethereal extract of mistletoe made into pills and given to eight patients suffering from tuberculous hæmoptysis, the dose being eight decigrammes daily. In seven of these patients the hæmoptysis was soon checked. The remaining patient derived no benefit, but in this case it was found after death that the hæmorrhage proceeded from a dilated vessel (aneurysm of Rasmussen) and was therefore not amenable to treatment. Under the influence of the ethereal extract of mistletoe the patients showed an obvious fall in the arterial blood pressure and an acceleration of the pulse, and M. Gaultier observed similar phenomena in animals to which he had given intravenous injections of a decoction of mistletoe in water. The utility of the plant in hæmoptysis appeared to be connected with its power of reducing the arterial blood pressure.

The Berck Hospital.

The budget of the Administration of the Assistance Publique for 1906 includes the sum of 300,000 francs to meet the expenses connected with the enlargement of the hospital at Berck. The sum is provided out of the profits of the *pari mutuel*.

July 10th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Medical Profession and the Telephone.

THE general use of the telephone has resulted in some unpleasant conflicts between patients and their medical advisers, as some of the former fail to understand that treatment "at a distance" is not within the power of a medical man. On the other hand, many patients find the telephone very convenient as a means of obtaining medical advice from a practitioner without having to pay his usual fee. In order to put an end to doubts as to the lawfulness or otherwise of charging for a "telephone consultation" when the circumstances made such a consultation possible—as, for instance, after an operation or before a patient's departure for a health resort—a case was brought into court where a patient, who had several times, even at night-time, asked his medical man for professional advice, refused to pay such fees. The judge decided that the advice must be paid for, whether it was given in the consulting room, or by letter, or by telephone, or at the bedside. The special knowledge of the practitioner, acquired with difficulty after long years of study, could never be a subject of "sweating"; it was the practitioner's duty to decide whether the case was such that he might safely give his further instructions by telephone after having seen the patient personally on a previous occasion. It is the intention of the branch divisions of the medical councils to require their members to charge for such consultations.

Angioneurotic Dermatitis in Hysterical Patients.

At a recent meeting of the Clinical Society Dr. Nobl showed two girls, aged 23 years, who presented some interesting phenomena on the skin of the thorax and the flexor surfaces of the extremities; one of them also had similar appearances on the abdomen. At the time of the demonstration only numbers of dark pigmented small scars were visible interrupted by bands of normal skin and by stripes of hard, elevated horny matter resembling keloid. When the patients were taken to the hospital (by a curious coincidence both went on the same day) the affected area was covered by numerous small vesicles which within 24 hours lost the epithelium and appeared partly as greyish-green scabs and partly as ulcers with a fibrinous superficial layer on them. They were diagnosed as zoster hysterical

gangrænous, and a careful examination revealed the presence of other markedly hysterical stigmata, such as hemianæsthesia of the right half of the body, a diminution of the field of vision on the temporal side, and pressure points on the mammae and abdomen. As there was a suspicion that the vesicular eruption might have been produced by artificial irritation, such as the use of chemicals, the thorax and the limbs were enveloped for five weeks in bandages of plaster-of-Paris and gelatin, which were renewed every four days. But beneath the bandages and while the patients were under close observation there appeared new vesicles which ran the same course and finally changed into gangrænous ulcers, so that the diagnosis was confirmed. One of the patients showed no after-effects but scars, whilst in the other girl long narrow bands of hypertrophied connective tissue running in the direction of the thoracic and intercostal nerves were beginning to develop in the place of the scars. The interest of these cases lies in the fact that the disease has been proved to be of endogenous origin. Several other observers have met with similar cases of obstinate dermatological irritation, mostly in females, but they were found to be due to the surreptitious use of caustics or sulphuric acid self-applied by hysterical subjects. The ingenuity of these patients has often baffled the most elaborate precautions of the medical men and the discovery that the lesions were self-inflicted was only made by maintaining the closest observation both night and day.

The Treatment of Tetanus.

In a lecture delivered before an invited society at the Franz Joseph Hospital in Vienna Dr. Lotheissen explained the method of treatment of tetanus and the prophylactic measures worked out by him recently. He employs the serum prepared at Höchst in Germany, which is twice or three times as strong as the French preparation, and he injects at least 100 antitoxin units. As regards the nature of the wounds which give rise to suspicion Dr. Lotheissen puts first in order the so-called "street wounds," mostly resulting from collision with cars or other vehicles, falls from horses, or motor car accidents; these wounds have been in contact with street dirt or mud; they are extensive and the tissues are bruised. Another item of importance is the depth of the wounds, because an injury inflicted by a long object, such as a piece of wood, may become infected, and in a deep wound exclusion of air is possible with consequent favourable conditions for the anaerobic micro-organism. The quantity and virulence of the dangerous material which has been introduced are unknown, so that large doses of the serum are required even in prophylactic injections. As the serum is slowly but continuously excreted by the organism a repetition of the injection is desirable. Dr. Lotheissen generally gives a second dose after one week if suppuration and fever continue. Acting on this plan he has during the last year seen only 12 cases of tetanus, all of which had also received prophylactic injections, whereas in former years the cases numbered 47, 71, 35, and 58. The onset of the tetanus in the last-named 12 cases is no doubt due either to the injections having been given too late or to the serum being too weak. At any rate, the attacks were decidedly milder than in former years, consisting merely of some spasmodic attacks of the masseter muscles and of the intercostal and abdominal muscles. In one case a scarlatiniform rash was visible for three days but no albuminuria or swellings of the joints was noted. One case ended fatally; the patient was a man whose left arm had been smashed by the discharge of a gun and he was not taken to the hospital until a fortnight after the accident, when the virus had no doubt already taken a firm hold on the nervous tissues.

The Value of the Abdominal Route in Operations for Uterine Cancer.

At a recent meeting of the Gynecological Society the respective values of the vaginal and the abdominal operation in cases of uterine cancer were compared and the majority of surgeons with an extensive experience on the subject expressed themselves in favour of the abdominal route. An interesting formula for the exact valuation was produced by Dr. Waldstein who declared that there is only one way to find out what the prognosis of the disease is. Professor Wertheim and Professor Schauta, who act both on the same lines, operate upon 50 per cent. of the women presenting themselves with uterine mischief and both clinics have 60 per cent. of relative recoveries or at least of freedom from relapse for more than five years. The mortality, which was formerly 15

per cent., has been reduced to 9 per cent. by shortening the duration of the anesthesia. All preparations are made on the patient in the stage of incipient narcosis, whilst the actual anesthesia is reserved only for the operation *sensu strictiori*. Oxygen is administered every now and then. Taking all data into consideration, the percentage of absolute recovery is only 11, which means that of every 100 women suffering from uterine cancer only 11 may (with present methods) be alive after five years without recurrence of the disease, whilst the remaining 89 die from the disease or from the operation or have to undergo further operations. The patients have been under observation for the last eight years. The plan adopted has for its object the eradication of the neoplasm and all deposits in the body by extirpation of all lymphatics connected with the primary and secondary nodules.

The Enamelling of Household Utensils.

The Ministry of the Interior has published some new regulations concerning the enamelling of articles coming in contact with food for human use. No measures for solid or liquid food and no table utensils may be coated with an enamel containing antimony or zinc. If this admixture be present in any such article all material at the factory where it was made is liable to be seized and destroyed. A similar regulation applies also to toys and to wrappers or boxes for tea, coffee, and tobacco.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Exposure of the Beef-packing Frauds.

THE public papers are acknowledging the fact that THE LANCET made the first exposure of the disgusting practices of the great Beef Trusts of Chicago through the investigations of its Special Commissioner. A leading paper quotes from the articles in THE LANCET of Jan. 7th and 14th, 1905, the most unqualified condemnation of the beef-packers' methods and remarks that these published facts of a year ago prove that the "Beef Trust has had its warnings again and again and has deliberately closed its ears to them." It adds: "There has been time since THE LANCET'S disclosure to replace the whole outfit of abattoirs at Chicago with abattoirs, but instead of profiting by the warning the Trust sneered at the disclosures and said that THE LANCET'S man was behind the times." It is admitted that the exposure by THE LANCET led to the recent investigations by separate individuals and finally to the inspections ordered by the President. The reform which will be forced by this exposure, both by public opinion and legislation, will be of world-wide importance.

Tuberculosis a Cause of Divorce.

The Superior Court of California has granted an application for divorce on the ground of pulmonary tuberculosis. A wife applied for divorce and in her application alleged that before the marriage was contracted she asked her prospective husband if he was perfectly sound and healthy and received every assurance that he was free from disease. Subsequently, after the marriage was consummated, it was proven that he was suffering from tuberculosis and the court held that the existence of this disease was sufficient to warrant the annulment of the marriage.

Regulation of the Use of Opium in the Philippines.

An Act of Congress provides that after March 1st, 1908, it shall be unlawful to import opium into the Philippines in whatever form, except by the Government, and for medicinal purposes only, and that at no time shall it be lawful to sell opium to any native of the Philippine Islands except for medicinal purposes. To regulate the traffic in opium until 1908 the Philippine Commission has passed a stringent law of which the following are some of the more important provisions: only Chinese long addicted to the use of the drug are permitted to use opium in any of its forms, and they must make formal application, and then the drug can be used only in the residence of the user; it can be sold and delivered only to licensed physicians, pharmacists, and dealers; physicians may prescribe opium as a medicine, but any physician who prescribes it for patients whose physical

condition does not require it shall have his licence to practise medicine revoked and shall be punished by a fine of not less than \$125 nor more than \$500, or by imprisonment for not less than six months nor more than one year. Licensed pharmacists and dealers are placed under the most rigid restrictions in the sale of opium.

Fatalities in Athletic Games.

With the opening season comes the annual discussion of the fatalities and proprieties of athletic games. One of the most trustworthy collections of statistics of these fatalities for the year 1905 was recently presented to the Norwegian Hospital Alumni Association. From this paper it appears that the whole number of deaths collected was 128, of which 50 were due to diseases and 78 to accidents of different kinds. Of the accidental deaths football was the game mentioned in 28 cases; baseball in 12; horse-racing in nine; boxing in six; gymnasium feats in three; and auto-driving in two; the other fatalities were equally divided between golf, hammer-throwing, bicycle coasting, hand ball, polo playing, and wrestling. Of the accidental deaths the average age was 20 years. The causes of death in football were: abdominal injuries, seven; dislocation of the spine with paralysis, three; concussion of the brain, five; fracture of the skull, five; cerebral hemorrhage, two; fracture of a rib with wound of the heart by spicula, two; and fracture of the spine, one. The causes of death in baseball were: blow over the cardiac area, five; head injuries, four; blow over the abdomen, one; and heart failure while running, one. Fractures of the skull were the cause of death in nine jockeys. In regard to the current opinion that athletics impair the heart Dr. Anderson, of Yale University, states that there have been 51 deaths of Yale athletes out of a total of 761, with heart disease as a cause in but two cases. Dr. Nicols and Dr. Smith, physicians to the football squad of Harvard University during the last football season, extending from Sept. 14th to Nov. 25th, 1905, report the list of injuries of every kind and grade as 145. They conclude that the number, severity, and permanence of the injuries received in playing football are very much greater than is generally credited; that the injuries are unavoidable, for as many are received in practice as in competition; that the proportion of injuries is incomparably greater in football than in any other of the major sports; that the game does not develop the best type of men physically; and that the percentage on injury is much too great for any mere sport.

Rockefeller Institute Scholarships.

The Rockefeller Institute for Medical Research has offered scholarships to assist investigations in experimental pathology, bacteriology, medical zoology, physiology and pharmacology, and physiologic and pathologic chemistry to be carried on in the laboratories of the Institute in New York City. The value of these scholarships ranges from \$600 to \$1000. They are open to men and women who are properly qualified to undertake research work in any of these departments and who will devote their entire time to study. The term of service begins preferably on Oct. 1st, but by special arrangement may begin at another time.

The Condition of the Air of the Subways.

The public complaints of the foulness of the air of the subways has led to an investigation with the following results. Chemical analysis of the dust showed that it contained 61.30 per cent. of iron, nearly all of which was in a metallic state; there was 21.94 per cent. of organic matter, consisting of particles of animal and vegetable origin; 15.58 per cent. of silica and other matters insoluble in acid; and 1.18 per cent. of oil. The average of a considerable number of determinations of the weight of dust suspended in the air was 61.6 milligrammes per 1000 cubic feet of air. The origin of the subway dust is attributed in part to the street from which it is drawn by suction, in part to the wear and tear of materials of construction, but a considerable amount is pulverized metal, ground up by the operations of the trains. The cause of the most prominent odours has been the lubricating oil used on the trains, the broken stone ballast of the roadbed, and worthless proprietary disinfectants used in the toilets. The railroad companies are engaged in introducing means of relieving the subways of the offensive and unhealthy atmosphere which now render them objectionable as routes of travel.

June 24th.

Obituary.

JOHN WINTER DRYLAND, M.R.C.S. ENG.,
L.S.A. LOND., J.P.

By the death of John Winter Dryland, which occurred on June 24th, unexpectedly at the last although he had been in failing health for some time, Kettering has to mourn the loss of a well-known and beloved medical practitioner and of a citizen to whom the welfare of the town wherein he had spent his life's work was always a matter of special interest. Mr. Dryland was born at Newbury, Berkshire, in 1833, and was educated at Totteridge School and at Paris. He received his medical education partly at Brighton and partly at Guy's Hospital. He qualified in 1855 and soon afterwards was appointed resident surgeon to the Reading Dispensary. Some two years later he resigned this post and went to Kettering as assistant to the late Mr. Wyman. Within a few months Mr. Wyman died and in 1858 Mr. Dryland purchased the practice and the house. In addition to having a large private practice Mr. Dryland held a number of public appointments. In 1859 he was appointed medical officer to the Kettering union, a post which he continued to hold till within a few months of his death. He was also medical officer to the union infirmary, a public vaccinator, and medical officer of health of Kettering. It was upon his advice that some years ago the Kettering board of guardians erected spacious buildings on land at the rear of the workhouse for use as a hospital for cases of tuberculosis and as a general infirmary. Since his appointment as medical officer of health in 1872 the sanitary conditions of Kettering have been greatly improved and he was, in addition, president of the local district nursing association and a member of the honorary staff of the General Hospital. It was mainly owing to his advocacy that the building of the isolation hospital was due. In 1903 he was placed upon the commission of the peace for the county of Northampton.

Besides the work connected with all the above mentioned offices Mr. Dryland took a deep interest in ambulance work and was never tired of instructing the railway men of Kettering in this subject, while it was he who delivered the first ambulance lecture ever given in Northamptonshire to a class held in connexion with the Kettering Church Institute. Just before his death he was created an honorary associate of the Order of St. John of Jerusalem. As regards his private practice he, like many another general practitioner, often had to undertake urgency operations of no light character in circumstances which were by no means favourable to good results and with no other assistance but a layman, but in 48 years of practice he only lost two patients after amputations.

Mr. Dryland was a Conservative and Churchman, and on June 27th his body was conveyed to the parish church where a short office was said. On the morning of June 28th the Holy Communion was said, and later in the day the interment took place in Kettering cemetery. The first part of the burial office was sung in the church, the congregation, besides the members of the family, including representatives of all the public bodies of the town. After the lesson the body was carried in procession to the cemetery where it was received by the rector of Kettering and other clergy. Mr. Dryland was twice married. He has left three daughters and two sons, one of whom, Mr. Leslie Winter Dryland, is in the medical profession.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Barthélemy, physician to the St. Lazare Hospital, Paris.—Dr. Josias, physician to the Paris hospitals.—Dr. Charles W. Allen, professor of dermatology in the New York Post-Graduate School and Hospital.—Dr. Hirschberg, a well known German authority on medical statistics.—Dr. Maurice Coote, formerly physician to the Marseilles hospitals.—Dr. Giulio Obici, *privat-docent* of mental diseases in the University of Padua.—Dr. Fritz Schaudinn of the Hamburg Institute of Tropical Medicine, at the age of 35 years. He was the first to recognise the existence of *spirochaeta pallida* in the plasma and secretions of syphilitic patients. Some years

ago, in conjunction with Dr. E. von Leyden, he discovered a new protozoon, *Leydenia gemmipara*, in the ascitic fluid of a case of cancer.—Dr. Friedrich Hegelmaier, emeritus professor of botany in the University of Tübingen, at the age of 72 years.—Dr. Ludwig Ebner, extraordinary professor of surgery in the University of Gratz, after an operation on the throat.

THE ROYAL VISIT TO NEWCASTLE.

His Majesty the King, accompanied by the Queen, arrived at Newcastle on Wednesday last to inaugurate the formal opening of the new buildings of the Armstrong College and the Royal Infirmary. The weather was unfortunately very bad but despite this drawback enormous crowds were assembled to welcome their Majesties and the utmost enthusiasm prevailed.

Their Majesties were met at the Central Station by the Mayor, Mr. J. B. Ellis (now Sir Joseph Baxter Ellis and Lord Mayor), the Duke of Northumberland, Lord Lieutenant of the County, Sir Mark Palmer, chairman of the Newcastle Chamber of Commerce, and other influential citizens, and after receiving addresses and bouquets drove to the Armstrong College, where they were received by Sir Isambard Owen, the Principal, Dean Kitchin, the Warden, and Mr. W. H. Knowles, the architect, who were supported by an influential array of north country notables. After the presentation of many interested in the College His Majesty declared the new buildings open in a short but eloquent speech, testifying to his admiration of the structure and his belief that the admirable facilities afforded for acquiring knowledge would give the inhabitants of Newcastle special opportunities of providing their children with valuable intellectual training. The College professors and students having presented addresses, the Queen accepted a casket made on the premises and, with the King, witnessed several interesting experiments in Professor Thornton's electrical laboratory.

By the time their Majesties reached the scene of the second great function of the day the weather had much improved. Their Majesties were received at the entrance of the infirmary by Lord Armstrong, chairman of the house committee; Sir George Hare Philipson, Sir Riley Lord, the principal members of the hospital staff, and the joint architects, Mr. W. L. Newcombe and Mr. Percy Adams. Lord Armstrong having read an address in which he stated briefly the history of the foundation and re-foundation of the infirmary, the King, in a reply of real eloquence, testified his sincere gratification at seeing the completion of the magnificent structure henceforth to be known as the Royal Victoria Infirmary. He alluded to the grand generosity of the large donors who had contributed to the fund as well as to the substantial pecuniary support supplied by the workers of the city, and expressed his pleasure in agreeing to the suggestion that two of the wards should be named "Edward VII. Ward" and "Queen Alexandra Ward" respectively. The Bishop of Durham having offered up prayer, the King declared the Royal Victoria Infirmary open. Many presentations were made, among those thus honoured being the Members for the borough, Mr. W. Hudson and Mr. Thomas Cairns, and Mr. G. J. Frampton, R.A., the sculptor of the statue of Queen Victoria which stands in front of the new infirmary.

His Majesty then conferred the honour of knighthood upon the Lord Mayor, who has three times served as mayor of the city. The departing drive of their Majesties to the railway station was the occasion of enthusiastic public expressions of loyalty.

¹ We tell this interesting story in a leading article this week, p. 100.

PRESENTATION TO A MEDICAL PRACTITIONER.—

The members of the Harrogate (Yorks) branch of the St. John Ambulance Association recently presented Mr. E. Carnell, M.R.C.S. Eng., L.R.C.P. Irel., D.P.H. R.C.P.S. Irel., with a silver and ivory paper-knife as a mark of appreciation of his services as honorary lecturer.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—The following gentlemen passed the second examination in anatomy and physiology held recently:—

Edward Bruce Allnutt, St. Bartholomew's Hospital; Manekjee Dhanjishaw Anklesaria, L.M. & S., Bombay; Tom Chamney Russell Archer, St. Thomas's Hospital; John Lee Atkinson, Guy's Hospital; Charles William Tresidder Baldwin, Charing Cross Hospital; Jehangir Cowasjee Balsara, L.M. & S., L.R.C.P. & S. Edin., Bombay; Ernest Cuthbert Barnett, New Zealand; Donald Maxwell Cox, Charing Cross Hospital; Ernest Edgar Davies, University College, Bristol; Archibald Wallace Duncan, St. Mary's Hospital; Evau Richard Evans, St. Bartholomew's Hospital; Walter Andrew Fernando, Ceylon and King's College; Philip Charles Field, University College, Bristol; Richard Sydney Graham, St. Mary's Hospital; Guy Fleetwood Haycraft, Guy's Hospital; Martin Hallam, Sheffield University; James Frank Hoare, University College Hospital; Maurice Lionel Corrie Irvine, St. Thomas's Hospital; John Lawrence Johnston, Guy's Hospital; Walter Foulkes Jones, B.A. Cantab., Cambridge University, St. George's and King's College Hospitals; Abdus Sattar Khan, L.M. & S., Calcutta; Lafat Husain Khan, Bombay and St. Bartholomew's Hospital; Henry Goff Kilner, Middlesex Hospital; Framrose Kolaporewalla, Bombay and Guy's Hospital; Russell Hardy Sidney Marshall, St. Mary's Hospital; Charles Anderson Meaden, St. Bartholomew's Hospital; John Cecil Wilson Methven, London Hospital; James Knowles Milligan, St. Thomas's Hospital; Frank Cyril Morgan, University College, Bristol; Albert Edgar Nicholls, University College, Cardiff; Frederick Cecil Nichols, Bristol; Richard Goodhart Oram, Guy's Hospital; William Robert Parkinson, Otago and St. Thomas's Hospital; Guy Harcourt Peall, Guy's Hospital; Charles Arnold Pemberton, Otago and Middlesex Hospital; Arthur Thomas Pitts, L.D.S., Middlesex Hospital; Quintin Hume Richardson, Guy's Hospital; Archer Ryland, St. Bartholomew's Hospital; Frank Stuart Tamplin, St. George's and King's College Hospitals; Jocelyn Langton Waller, St. Mary's Hospital; Thomas Newlands Watt, Otago; Walter Weir, St. Thomas's Hospital; Charles Whitaker, St. Bartholomew's Hospital; Cyril Underwood Whitney, Westminster Hospital; and Arthur John Ormsby Wigmore, University College, Bristol.

SOCIETY OF APOTHECARIES OF LONDON.—At the primary examination held recently the following candidates passed in the subjects indicated:—

PART I.

Biology.—C. R. Corfield, Manchester; and E. M. Johnstone, A. Jonathan, and A. Singha, Royal Free Hospital.
Chemistry.—J. B. Holmes, Manchester; and A. Singha, Royal Free Hospital.
Materia Medica and Pharmacy.—C. R. Corfield, Manchester; W. H. Hooton, Leeds; B. Robertshaw, Manchester; and H. H. Smith, Royal Free Hospital.

PART II.

Anatomy.—R. E. Clarke, London Hospital; A. H. C. Dawes, Westminster Hospital; B. McDermott, Guy's Hospital; G. S. Richardson, Leeds; S. H. Scott, Cambridge and London Hospital; and T. A. F. Tyrrell, St. Mary's Hospital.
Physiology.—E. C. Banks and A. Baxendale, Manchester; R. E. Clarke, London Hospital; A. H. C. Dawes, Westminster Hospital; B. McDermott, Guy's Hospital; M. Remers, Manchester; and T. A. F. Tyrrell, St. Mary's Hospital.

UNIVERSITY OF OXFORD.—The following degrees in Medicine have been conferred:—

D.M.—W. H. Wilson, Keeble College.
B.M., B.Ch.—A. G. J. Thompson, Queen's College; O. A. R. Berkeley-Hill, Trinity College; and S. Nockolds and L. J. J. Orpen, Keeble College.

UNIVERSITY OF GLASGOW.—In the fourth (final) professional examination the following have satisfied the examiners:—

M.B., C.M.—*Robert Stewart M'Kim, M.A.
M.B., Ch.B.—James Montgomery Anderson, †John Anderson, M.A., B.Sc., Thomas Barbour, M.A., B.Sc., George Duncan Morrison Beaton, Charles Burns, John Miller Hopkins Caldwell, William Rome Cammock, George Campbell, William Archibald Campbell, Henry Howard Christie, John Sowers Clark, M.A., James Goutie, Thomas Lawson Craig, †Arthur Muir Crawford, †James Richard Drever, M.A., Ernest Milne, †Easton, William Gilbert, William Gillilan, †Arnold Harris Gray, Robert Neil Guthrie, Charles Francis Dyer Hammond, William Towers Hardie, Robert M'Cowen Hill, Alexander Hunter, Archibald Yule Hutchison, John Kay, James Duntop Kidd, William Hendrie Kirk, Alexander M'Call, Thomas M'Cririck, M.A., B.Sc., David Macdonald, †James M'Farlane, John Robert M'Givray, M.A., B.Sc., Norman M'Kellar, William Ferguson MacKenzie, Norman Smith MacNaughtan, Allister Argyre Campbell M'Neill, †Elizabeth Maud M'Vail, †Andrew Alexander M'Whan, Florence Mann, William Hislop Manson M.A., Robert Marshall, John Miller, †Peter Mitchell, M.A., Edith Ovaraby, James Hogg Paul, †Iagnes Picken, M.A., Alexander MacMillan Pollock, Thomas Hood Rankin, Vera Dagmar Reiss, Frederick Gordon Robertson, †William James Rutherford, William Hermann Sieger, †William Smellie, Thomas Baillie Smith, †James Stevenson, †John Stevenson, Thomas Strain, David Laurence Tate, *Charles

Samson Thomson, George Haswell Wilson, James Wyper, John Young (Mount Vernon), and Morris Youdelevitz Young.
 Passed with distinction in: (a) Surgery and Clinical Surgery, (b) Practice of Medicine and Clinical Medicine. † (a) Practice of Medicine and Clinical Medicine, (b) Midwifery. ‡ Surgery and Clinical Surgery. § Practice of Medicine and Clinical Medicine. ¶ Midwifery.

TRINITY COLLEGE, DUBLIN.—At the intermediate medical examination held in Trinity term the following candidates were successful:—

Part II.—Richard P. Hadden, Samuel F. A. Charles, John L. Phibbs, Henry H. Ormsby, Albert V. J. Richardson, Herbert V. Stanley, Frederick A. Anderson, Charles W. Laird, George Halpin, George B. McHutcheson, Gerald G. Mccredy, Robert de C. Wheeler, William E. M. Armstrong, Edward J. H. Garstin, Frederick H. Sayers, Duncan F. Hunter, Henry R. Kenny, Arthur H. Laird, Harold S. Sugars, Richard T. Attridge, John C. Baker, William H. Sutcliffe, William H. M'Carthy, and Frank Smartt.

The following medical scholarships have been awarded:—Anatomy and Institutes of Medicine: Johannes C. Pretorius, Trinity College Scholarship; and Samuel F. A. Charles, Stewart Scholarship. Physics, Chemistry, Botany, and Zoology: Arnold K. Henry, Trinity College Scholarship; and David Duff, Stewart Scholarship. Purser Medal in Institutes of Medicine: Richard P. Hadden.

FOREIGN UNIVERSITY INTELLIGENCE.—*Rasle*: Dr. Friedrich Suter has been recognised as *privat-docent* of Urology and the Surgery of the Urinary Passages.—*Berlin*: Surgeon-General Kern of the Military Medical Academy has been appointed Professor of Pharmacognosy in the University.—*Graz*: Dr. Oskar Eberstaller, municipal medical officer, has been granted the rank and title of an Extraordinary Professor in the University.—*Lund*: Dr. A. Dalén has been promoted to an Extraordinary Professorship of Ophthalmology.—*Moscow*: Dr. Minakoff has been promoted to the Ordinary Professorship of Forensic Medicine.—*Prague (German University)*: Dr. Otto Piffil has been appointed Extraordinary Professor of Otolaryngology and Rhinology.—*Tübingen*: Dr. Baerler has been recognised as *privat-docent* of Physiology.—*Würzburg*: Dr. Ritter von Rindfleisch is retiring from the charge of the Pathological Institute and from the active duties of his chair.

WIGAN INFIRMARY—Mr. W. Mitchell Rookcroft, honorary surgeon to the Wigan Infirmary, has been appointed chairman of the board of management for the ensuing year.

CITY ORTHOPÆDIC HOSPITAL: AMALGAMATION SCHEME.—A special general meeting of the governors of this hospital was held in the board room of the hospital on July 11th, under the presidency of Mr W. H. Brighton (solicitor to the hospital), when it was resolved—

That the amended proposals of the council of King Edward's Hospital Fund for amalgamation with the Royal and National Orthopædic Hospital be accepted.

Mr. John Poland, F.R.C.S. Eng., having pointed out that only surgeons possessing the qualification of F.R.C.S. Eng. would be eligible for election on the staff of the amalgamated hospital, it was decided to ask the trustees when making arrangements for the amalgamation to secure if possible that the present members of the medical staff of the City Orthopædic Hospital should be eligible for the new institution. Mr. Chisholm Williams, F.R.C.S. Edin., and Mr. Noble Smith, F.R.C.S. Edin., took part in the discussion.

GUY'S HOSPITAL.—The distribution of prizes at Guy's Hospital on July 4th by Sir W. Cameron Gull was marked not only by the plain speaking of that gentleman on the subject of vivisection but also by the great interest shown in the Gordon Museum for pathological specimens. Sir W. C. Gull in the course of his address after delivering the prizes to the successful students declared that medical practitioners must keep abreast of the advances in medical science. He expressed surprise at the apathy of the public in regard to medical schools and observed that the reason might be found in the influence of that noisy section of the community which was endeavouring to persuade the public that vivisection was a great evil. Continuing, he declared that as for himself he fully believed that vivisection was absolutely essential to adequate training in medical science and he added that Guy's Hospital could speak freely on the matter, for the governors had never supported the school out of the funds subscribed for the hospital. He concluded with the assertion that if the public would realise the great needs of the medical school he was sure that they would be more generous. The Gordon Museum was presented to Guy's Hospital by Mr.

Robert Gordon, a governor of the hospital, and was opened in 1905. It is arranged in four bays, top-lighted and inter-communicating. It contains 13,500 superficial feet for the accommodation of specimens on shelves and in show-cases. Here are housed the collection of pathological specimens for which the school at Guy's Hospital has always been famous and the unique collection of wax models, fashioned by Joseph Towne from dissections by John Hilton. Attention was also directed to a collection of old instruments and other objects of historical or antiquarian interest connected with Guy's Hospital.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JULY 5TH.

Switzerland and Vaccination.

Mr. LUTTON asked the Secretary of State for Foreign Affairs whether he would ascertain and inform the House which of the cantons constituting the Swiss Republic had abolished compulsory vaccination and which of them still enforced it; and whether the population of the cantons in which compulsion had been retained showed a liability to small-pox greater or less than the liability shown by the population of the cantons which had abolished compulsion.—Mr. HUNCEMAN, who replied, said: Our latest information (1900) respecting vaccination law in Switzerland represents two cantons as having never passed such law, nine cantons as having repealed a former vaccination law, two cantons as not enforcing their vaccination law, and 12 cantons as having vaccination law more or less in force. Switzerland in recent years had not suffered much small-pox; in the period 1900-04 (inclusive) there occurred in that country some 800 cases only of the disease. These cases were fairly evenly distributed between the 13 cantons not enforcing and the 12 cantons giving effect to vaccination law. But though the disease might be regarded as fairly evenly distributed in the five years in question over the whole population, it affected very differently children under ten years of age. Of the 800 old small-pox attacks 180 were of children under ten years of age, and of these 180 children 26 were recorded as vaccinated, while 154 were returned as unvaccinated. Of the 26 vaccinated children taking small-pox none died, whereas of the 154 recorded as unvaccinated and attacked by the disease 27 died.

Enteric Fever at an Asylum.

Mr. COOPER asked the President of the Local Government Board whether his attention had been directed to the outbreak of enteric fever at the Belmont Imbecile Asylum, Sutton; whether any delay arose in notifying the disease to the local sanitary authority; and whether the cause of the infection had been discovered.—Mr. JOHN BURNS answered: I am aware of the outbreak referred to. There was some delay in the notification to the sanitary authority. That was due to the fact that many of the cases, especially the earlier ones, presented peculiar symptoms and that it was not until bacteriological tests had been applied that a diagnosis of enteric fever was arrived at.

MONDAY, JULY 9TH.

The Public and Infectious Hospitals.

Sir JOHN JARDINE asked the President of the Local Government Board whether he was aware that, although the rules of the Metropolitan Asylum Board strongly discountenanced the making of personal inquiries at infectious hospitals by the friends of patients and stated that all inquiries must be made in writing to the medical superintendent, delay frequently occurred in answering such inquiries, and information was not given either to the nearest relative or to the certifying medical attendant as to the diagnosis of the case after admission; whether he was aware of instances in which, from misunderstanding or ignorance of the rules, or other causes, relatives of patients received no official information whatever during the whole period of detention of the patient; and whether, as the removal of patients was practically compulsory, he would cause a circular to be issued to the Metropolitan Asylum Board and other similar authorities outside the London area, prescribing forms for brief reports to be sent to relatives at prescribed and frequent intervals, whether formally applied for or not, and for a report on the diagnosis and bacteriological examination of the case to be sent to the medical practitioner by whom the case was certified.—Mr. JOHN BURNS answered: The managers of the Metropolitan Asylum District have, as I am informed, no reason to believe that delay frequently occurs in answering letters of inquiry concerning patients in their hospitals nor have I received complaints on the subject. I understand that the certifying medical practitioner is always informed by the medical superintendent of the hospital when the latter does not agree with the certified diagnosis of the case. Notice of the arrival of a patient at a hospital of the managers is always sent to the parents or other nearest known relative or friend. Extracts from the regulations are printed on the notice and these show that inquiries as to the condition of the patient may be made in writing to the medical superintendent, who will send an early reply, and that should the patient become dangerously ill notice will be sent to the nearest known relative or friend with an intimation that the patient may be visited. I believe, too, that as regards the hospitals of local authorities outside London it is the general rule to give notice when the patient is dangerously ill. As at present advised, I do not think there is sufficient ground for adopting the suggestion in the last part of the question which would involve considerable expense as well as labour to those concerned. I think that the object which my honourable friend has in view will be sufficiently met by the public attention which will be drawn to the matter by his question.

Boards of Guardians and Fees for Primary Vaccination.

Mr. HUDSON asked the President of the Local Government Board whether his attention had been called to the existing scale of fees for

primary vaccination by the several boards of guardians, and whether, in view of the financial burden imposed on them, he could take immediate steps to alter the scale of fees and cost of administration of the Vaccination laws.—Mr. JOHN BURNS replied: Yes, sir; my attention has been called to this subject and it is receiving my consideration.

Australian Tinned Meat Trade.

Mr. WILLIAM REDMOND asked the Under Secretary of State for the Colonies whether the Colonial Office had received any representations as to the position of the tinned meat trade in New South Wales; and whether he had any official information that the system of inspection in operation in Australia was so rigorous and careful that the occurrence of any abuse was impossible, and that consequently there had been no complaint whatever as to the excellence of the article supplied by the Australian trade.—Mr. CHURCHILL replied: Since the honourable Member's question was put to me on July 2nd a letter has been received from the Agent-General for New South Wales pointing out that special care is exercised by the New South Wales Government that only healthy beasts are slaughtered for food, and both in freezing and canning works every precaution is taken to insure that cleanly methods are adopted. All animals intended for human food are first of all inspected alive in the sale yards by Government veterinary experts. These inspectors are either veterinary surgeons or have passed a thorough examination in the detection of diseases both in live stock and meat. Subsequently the carcasses are inspected in the slaughter-houses which are also under Government control. In transit, in shops, and in other places frequent inspections are made and these extend in every instance to the whole premises and to all meats or parts of the carcass. Not only this, but the utensils and appliances, in addition to the blood, offal, &c., are inspected, and were any breach of the regulations regarding cleanliness to occur the licence to such premises would be at once withdrawn. The Government inspectors have to make weekly reports with particulars of the numbers of cattle slaughtered. Not only has every slaughtering establishment to be licensed but every person intending to slaughter cattle for food has to give 12 hours' notice to the inspector to enable him to be present, a penalty of £5 being inflicted for every head of cattle which has been slaughtered without proper notice having been given. The laws against the slaughtering for food of any cattle that are in any way diseased are strict, and if an inspector finds the milk or spleen of any slaughtered animal to be diseased he causes the entire carcass to be removed and destroyed under penalty of a fine from £10 to £50. Any person taking such beast to slaughter is liable to imprisonment for a term not exceeding two years, with or without hard labour, and anyone attempting to sell such diseased meat is liable to a long term of imprisonment. In the establishments where meat is being prepared for canning, &c., the regulations are especially strict. I desire to correct a mistake which was unfortunately made in my answer to the honourable Member's question on July 2nd. I then stated that no tinned meat was exported from New South Wales to this country. I should have stated that no boneless meat was exported. Tinned meat is imported from New South Wales and also from Queensland in considerable quantities and in smaller quantities from South Australia and Victoria. I understand that in the principal works in Australia where the preserved meat industry is carried on the beasts are killed purely and solely for preserving purposes and only the finest parts of them go into the tins.

TUESDAY, JULY 10TH.

Health Conditions of Tin-plate Manufacture.

Mr. SUMMERBELL asked the Secretary of State for the Home Department whether his attention had been called to the fact that there were 250,000 persons employed in the manufacture of tin- and black-plate; that the manufacture of such articles took place under unhealthy and dangerous conditions; and whether it was his intention to afford more inspection to tin-plate works.—Mr. GLADSTONE answered: The number of persons employed in the manufacture of black- and tin-plate in this country is, I think, very much smaller than that stated in the question. I am unable to give the exact figures, as in the Factory Department's tables the industry is included under the heading "Conversion of iron into steel, &c." but the total number under this heading in 1901 was 138,693 and the black- and tin-plate workers would form only a small part. According to the figures of the 1901 census the number employed in the manufacture of tin-plate was just over 15,000. The industry was made the subject of special inquiry in the years 1899 to 1901 and a conference was held with the manufacturers at which certain suggestions for protecting the workers against injurious fumes and dust were discussed. I will call for a special report as to the progress that has been made since then and the present conditions of the industry.

BOOKS, ETC., RECEIVED.

BAILLIÈRE ET FILS, J. B., 19, Rue Hautefeuille, Paris.

Le Rein Mobile. Par Félix Legueux, Professeur agrégé à la Faculté de Médecine de Paris, Chirurgien de l'Hôpital Tenon. ("Les Actualités Médicales" Series.) Price Fr. 1.50

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

COOPER, R. HIGHAM, L.S.A., has been appointed Radiographer to the Evelina Hospital for Sick Children.
FERGUSON, ROBERT J., M.D., M.Ch., M.A.O.R.U.I., F.R.C.S. Eng., has been appointed Gynecological Registrar to the Kenington General Hospital.
GRAHAM, J., M.B., Ch.B. Edin., has been appointed Clinical Assistant to the Chelsea Hospital for Women.
HUSTLER, G. H., M.B., Ch.B. Leeds, has been appointed Assistant House Surgeon at the Royal Devon and Exeter Hospital, Exeter.
LAING, E. A. R., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Rochford District of the county of Essex.
MACKINTOSH, F. I., M.B., M.S. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Strathmiglo District of the county of Fife.
ROSE, FRANK A., M.B., B.C. Cantab., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Hospital for Diseases of the Throat, Nose, and Ear, Golden-square.
SAWYER, JAMES E. H., M.D. Oxon., M.R.C.P. Lond., has been appointed Casualty Assistant Physician to the General Hospital, Birmingham.
SHEPPARD, AMY, M.B. Lond., D.P.H. Cantab., has been appointed Ophthalmic Surgeon to the New Hospital for Women and Children, Euston-road.
STEVENS, W. MITCHELL, M.D. Lond., M.R.C.P. Lond., has been appointed Lecturer in Materia Medica and Pharmacology to the University College of South Wales and Monmouthshire, Cardiff.
TRIBE, R. H., M.R.C.S., L.R.C.P. Lond., has been appointed Anaesthetist to the Victoria Hospital for Children, Chelsea.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BEVFREY, EAST RIDING LUNATIC ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, and washing.
BIRMINGHAM, UNIVERSITY OF.—Walter Myers Travelling Studentship. Value £150 for one year.
BRADFORD POOR-LAW UNION HOSPITAL AND WORKHOUSE.—Resident Assistant Medical Officer, unmarried. Salary £100, with rations, apartments, and washing.
BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, unmarried. Salary £100 per annum, with board and residence.
BRIGHTON, SUSSEX COUNTY HOSPITAL.—House Physician, unmarried. Salary £70 per annum, with board and residence.
BRIGHTON THROAT AND EAR HOSPITAL, Church-street, Queen's-road.—Non-resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.
BURNLEY, VICTORIA HOSPITAL.—Resident Medical Officer. Salary £100, with residence, board, and washing.
CAMBRIDGESHIRE, &c., ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £120 per annum, with board, lodging, and attendance.
CANCER HOSPITAL, Fulham-road, London, S.W.—Medical Officer in Charge of Electrical Department. Honorarium £26 6s. per annum.
CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary £50 a year, with board, apartments, and laundry.
CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £50 per annum, with board, residence, &c.
DERBY, DERBYSHIRE ROYAL INFIRMARY.—Assistant House Surgeon for six months. Salary £30, with board, residence, and washing.
DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant to the Resident Medical Officer for six months. Salary at rate of £50 a year, with board and lodging.
EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Pathologist and Registrar. Salary £100 per annum.
EGYPTIAN GOVERNMENT, MINISTRY OF EDUCATION.—Professor of Midwifery and Gynecology. Salary £400 a year. Also Medical Tutor and Registrar to Kaar-el-Ainy Hospital. Salary £400 a year.
EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, S.E.—Physician to Out-patients.
GLOUCESTER GENERAL INFIRMARY AND THE GLOUCESTERSHIRE EYE INSTITUTION.—Assistant House Surgeon for six months. Salary at rate of £30 per annum, with board, residence, and washing.
HARTLEPOOLS HOSPITAL.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

HERSFORD GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Physician, unmarried, for six months. Salary £20, with board and residence. Also Assistant Casualty Medical Officer, unmarried, for six months. Salary £20, with board and residence, &c. Also Radiographer.

HOSPITAL FOR SICK CHILDREN, Newcastle-on-Tyne.—Resident Medical Officer. Salary £100, with board, lodging, and laundry.

HOSPITAL FOR WOMEN, Soho-square, W.—Medical Registrar. Honorarium 25 guineas.

HULL ROYAL INFIRMARY.—Casualty House Surgeon. Salary £50 per annum, with board and lodging.

KENSINGTON GENERAL HOSPITAL, Bar's-court, S.W.—Junior House Physician for six months. Salary £40 per annum, with board, washing, and residence.

LEEDS, UNIVERSITY OF, SCHOOL OF DENTISTRY.—Lecturers in: (1) Dental Surgery; (2) Operative Dental Surgery; (3) Dental Anatomy and Physiology; and (4) Dental Mechanics.

LEITH HOSPITAL.—Honorary Assistant House Surgeon and Assistant House Physician, both for six months.

LINCOLN LUNATIC HOSPITAL.—Assistant Medical Officer. Salary £100, with board, &c.

LIVERPOOL EYE AND EAR INFIRMARY, Myrtle street, Liverpool.—House Surgeon. Salary £80 per annum, with board and residence.

LIVERPOOL, WEST DERBY UNION INFIRMARY.—Resident Medical Officer, unmarried. Salary £125 per annum, with board.

MANCHESTER MORSEBAY FEVER HOSPITAL.—Fourth Medical Assistant. Salary £100 per annum, with board, lodging, and washing.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—Assistant Medical Officer for the new Crossley Sanatorium. Salary £50 per annum, with board, apartments, and laundry.

MANCHESTER, UNIVERSITY OF.—Junior Demonstrator in Physiology. Salary £100, rising to £150 per annum. Also Lecturer in Dental Surgery. Also Lecturer in Dental Prosthetics.

NEWCASTLE, Co. Wicklow, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION FOR IRELAND.—Resident Medical Officer. Also Assistant Resident Medical Officer. Salaries £100 and £50 respectively, with residence, board, and laundry.

NORWICH, NORFOLK AND NORWICH HOSPITAL.—Surgeon and Assistant Surgeon.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Assistant House Surgeon for six months, renewable. Salary at rate of £50 per annum, with board, residence, and washing.

PRESTON ROYAL INFIRMARY.—Senior House Surgeon. Salary £100 per annum, with board, lodging, washing, &c.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £50 per annum, with board and lodging.

SHEFFIELD UNION HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with apartments, ration, &c.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon for six months. Salary at rate of £40 per annum, with board, washing, and residence.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—House Physician for six months. Honorarium £25, with board and lodging.

WEST RIDING ASYLUM, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £140, rising to £160, with board, &c.

WIDNES AND ETON ROYAL DISPENSARY AND INFIRMARY.—House Surgeon, unmarried. Salary £120 per annum, with residence, board, laundry, and attendance.

WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House Surgeon. Salary £70 per annum, with rooms, board, and washing.

WORCESTER GENERAL INFIRMARY.—House Physician. Salary £80 per annum, with board and residence.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Silgo, in the county of Sligo, and at Bly, in the county of Cambridge.

Births, Marriages, and Deaths.

BIRTHS.

COOPER.—On July 2nd, at Fownhope, Surbiton Hill, the wife of Harry Cooper, M.A., M.D., of a son.

CUNNINGHAM.—On July 7th, at Firenze, Malone Park, Belfast, the wife of H. H. B. Cunningham, M.D., F.R.C.S.I., of a daughter.

KING.—On July 10th, at St. Leonard's, Osmaston-road, Derby, to Dr. and Mrs. J. W. King, a son.

SPEIRS.—On June 29th, at The Cedars, Diss, the wife of Dr. H. Meredith Speirs, of a son.

MARRIAGES.

CUNNING—THIN.—On July 4th, at Trinity Presbyterian Church, Cloughton, Birkenhead, Joseph Cunning, F.R.C.S. Eng., to Annie B. Thin, M.B. Lond.

DIXON—ROBERTSON.—On July 5th, at St. Paul's Church, Brentford, Charles Frederick Lyne Dixon, M.D., M.R.C.S., to Jessie May Robertson, eldest daughter of Mrs. Newcombe of Clovelly, Boston-road, Brentford.

DEATH.

HILL.—On July 6th, at St. Keverne, Lyminster, Hants, William Robinson Hill, M.D., J.P., aged 70 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MR. TROUTBECK AND QUACKS.

WE have upon so many occasions felt compelled to differ seriously from Mr. Troutbeck's views upon matters medical that it is with all the more pleasure that we take the opportunity to praise him in connexion with his admirable remarks upon quacks, as delivered at an inquest recently held by him. The subject of the inquest was the death of a man named George Buckland who died from hæmorrhage caused by pulmonary tuberculosis. He was under the treatment by correspondence given by a quack establishment known as the Weidhaas Institute, Burgess Hill, Sussex. We have known of this place for some time as being run by a person calling himself Paul Weidhaas, although we have no information as to whether he is alive at the present date or not. The coroner, after remarking upon the various remedies recommended by the institute, which included such things as "calf packing" and "cat tea straw," said that the law was particularly tender to quacks, allowing them to practise and to make large fortunes out of wretchedly poor people who were suffering from mortal diseases and who therefore were tempted to try these so-called remedies. He did not suppose that the "treatment accelerated the man's death, but it certainly could have done him no good." Mr. Troutbeck's remarks are admirable, but we wish that he had included in his censures the proprietors of newspapers and magazines who never hesitate to publish advertisements of the most flagrant quack preparations. If the quack could not obtain advertisement of his wares in the daily press and in magazines his chances of inveigling dupes would be much diminished. Legal interference with quackery is not to be expected in the shape that our more ardent reformers anticipate, but those who hope to see all quacks obliged to pay a heavy licence to "practise" will receive encouragement from Mr. Troutbeck's attitude.

A POINT IN POOR-LAW.

To the Editors of THE LANCET.

SIRS.—There is no question that your ruling (in THE LANCET of July 7th) is correct that a Poor-law medical officer must attend paupers removed to an isolation hospital provided that that hospital is within his district and the paupers are *bona-fide* inhabitants of his district also. The service has been forced upon me twice. In one case I had for nearly a year to attend the inmates of an isolation hospital temporarily established in an empty house, fortunately for me situated near my house. When I tried to get some extra payment for my services I was warned privately not to press the claim as I should not get it, and it was pointed out that I had been a gainer to the extent of attending these people in well-appointed surroundings at a convenient distance when they might have been scattered all over a large and hilly district in miserable cottages. On another occasion a case of confluent small-pox occurred in a cottage four miles from me in the person of a well-to-do labourer; the practitioner who saw him first refused to attend him further after he had made the diagnosis and an order was served on me. A camp for small-pox was established in my district and this case and others were moved to it; I had to attend them and received no extra fee. There is nothing to prevent any district council, which is also a board of guardians, refusing to pay medical officers for its isolation hospital and compelling the inmates to pay for their own medical attendance or to be attended by the Poor-law medical officer; the latter cannot claim any payment for his services in such a case unless the patients reside out of his own district. This is not a satisfactory state of things both for Poor-law medical officers and the profession at large.

I am, Sirs, yours faithfully,
EDUAM.

July 7th, 1906.

CONCERNING POMEROYS.

THERE have been few more popular English novelists than the late Mrs. Henry Wood. The total circulation of her books was something colossal and although superior persons affected to regard them as being written rather for the domestic servant than the educated student she was a thoroughly good story teller and a shrewd observer of certain phases of English domestic life. She was not, however, a good delineator of people outside the middle and lower middle classes, her earls and baronets having a lurid tendency to fine language, ostentation, and crime. We remember one aristocratic family, "The Pomeroy of Pomeroy," who were described with extraordinary unction for the delectation of the pantry, who were recognised by the countryside as being of such superior clay that they received a sort of courtesy peage from their neighbours (for the Crown did not happen to have ennobled them), and who throughout a long novel betrayed a whole-hearted belief that a Pomeroy must be haughty and baronial and impossible. The characters seemed incredible, and yet Mrs. Henry Wood may not have overdrawn them, for we learn from a Southport paper that the Honourable Ernest Pomeroy—the coincidence of the name is a little striking—has been elected President of a League of Medical Freedom and that in a letter expressing sympathy with the general

objects of the league Mr. Pomeroy has said: "Medical men were more anxious for guineas than anything else and their various prescriptions are in the main harmful. If all doctors were crucified to-morrow and we were delivered from them and sanitary authorities, the general life would be healthier and happier." There spoke a genuine Pomeroy of Pomeroy as fashioned by Mrs. Henry Wood; there spoke a proof of the verisimilitude of characters which short-sighted critics have declared to have no counterpart in life. The haughty contempt for doctors and low scientific persons, the hale-me-this-fellow-to-a-dungeon attitude, and the crass stupidity of the sentiments make up a picture of the nobleman dear to the unlettered devoursers of fiction, and the many authors who toil in Mrs. Henry Wood's wake far in her wake—must be grateful to Mr. Ernest Pomeroy for justifying their portraiture of a type.

UNMANNERLY.

To the Editors of THE LANCET.

SIRS.—Upon reading the correspondence in THE LANCET of July 7th, p. 64, I was more than thunderstruck with the slur which "M.D. Lond." and one who is "on the staff of a hospital" tries to work off against the holders of the L.R.C.S., L.R.C.P. Edin.—"I might add as facts relevant to the issue that Dr. D is L.R.C.S. and L.R.C.P. Edin." "M.D. Lond." should know that there is a possibility of honourable men possessing the diploma of the Conjoint Board of Scotland. In no circumstance could you excuse Dr. D for his mistake or unmannerly conduct. But why should all "L.R.C.S., L.R.C.P. Edin." be classed in the same box with Dr. D. I have as much right to class all men who are "on the staff of a hospital" in the class which I shall now record and ask "M.D." if he is willing to be classed with such conduct. A patient of my own who was suffering from appendicitis required operation. Mr. A, as we shall call him, was asked by his employer to see Dr. B who operated upon Mr. A without even acquainting Dr. C, the present writer, of the fact. Of course Dr. B was "on the staff of a hospital." No doubt honourable conduct for gentlemen who are "on the staff of a hospital." Then here is a little more of my experience with M.B.'s. One, Dr. D, went the length of examining a patient of my own and prescribing for the patient without being asked and without fee. Honourable conduct, no doubt, for an M.B. Dr. E, who is an M.D., is very fond of frequenting hairdressers' shops and giving nicknames to all medical men in the district, he himself, no doubt, posing as the paragon of virtue. If "M.D." is willing to accept such conduct as honourable for M.B.'s and M.D.'s he should, at least, respect honourable men, though they belong to the L.R.C.S. & L.R.C.P. Edin. and not cast a slur upon all for one. I inclose my card.

I am, Sirs, yours faithfully,

July 9th, 1906.

L.R.C.S. & L.R.C.P. EDIN.

. We did not read "M.D. Lond.'s" letter as our correspondent L.R.C.S. & L.R.C.P. Edin. has done. "M.D. Lond.'s" allusion to Mr. D's diplomas and his own qualification and standing were made, it appeared to us, to show that it was unreasonable as well as rude of Mr. D to refuse a consultation in such uncompromising terms. We do not see in "M.D. Lond.'s" remark any classification of all L.R.C.S., L.R.C.P. Edins. "in the same box with Dr. D."—ED. L.

THE COUNTRY IN TOWN EXHIBITION.

THE object of the organisers of the Country in Town Exhibition, opened by Princess Christian on July 5th, was to show East Londoners what can be done to bring into the heart of such a grimy city as theirs something of the beauty, freshness, and inspiration of nature. The organisers have succeeded in their attempt and are to be congratulated upon the instructive and pleasing collection of animate and inanimate objects which they have brought together in the Whitechapel Art Gallery. The various exhibits, almost all of them, contain a lesson of profound interest for those who would like to see our streets and houses beautified by drawing upon the resources of a country rich above most in rural beauty. Accordingly we find exhibited most of the members of the vegetable kingdom that can be grown under the restricted conditions which prevail in the metropolis. The curator of the Chelsea Physic Garden, for example, showed a large collection of hardy ferns and Alpine and other plants of different characters which, for this reason or that, thrive, perhaps even come to perfection, in London. The famous garden of the Apothecaries' Society, however, has an airy site on the north bank of the river, the south bank in that neighbourhood being occupied by Battersea Park, and such an airy habitat gives it advantages that are not usually enjoyed in any city. Private firms show similar collections of plants, and if the pot-grown plants, witnesses of the love and tender care of the poor children of our slum schools and the blind children of one of our London County schools, do not turn out to be prize specimens from the flower-show point of view, they prove at any rate how much can be done by floriculture for homes otherwise lacking in brightness. The authorities of the Central Foundation School in Spital-square, E., send an interesting exhibit. The complaint is sometimes made that nature study cannot be carried out in schools in the midst of workshops and factories, but the teachers of this school show a remarkable testimony to the intelligence of their scholars. Maps have been made of such open spaces as there are in the district and the children are taken to these tiny cases, recording the observations made in their excursions both in

writing and graphically with crayon and brush. Many of the drawings are crude but they show how much of living nature can be seen under conditions where many people would see nothing. An excellent exhibit of Alpine plants was grown in window-boxes by Mr. Edward Lovett who also sent a photograph of a pot of edelweiss grown on the roof of the Bank of England. The paintings of native orchids, the originals of which were grown in frames by Mr. C. E. Clark, a schoolmaster at Hammersmith, are also very interesting. The exhibition, which is under the patronage of Her Majesty the Queen, is open free daily from 12 noon till 10 p.m. until July 19th.

THE PREVENTION OF ANTHRAX.

WE have received from the Home Office a placard of about 20 inches by 12, printed in large clear type, briefly descriptive of the cause of anthrax, its propagation, and the naked-eye appearance of the lesion when the infection takes place on the surface of the skin. At the top of the placard are illustrations of three patches of skin printed in colours of about six centimetres square, showing the common appearance of anthrax on the first or second day, on the third or fourth day, and at a later stage. The placard has been prepared by Dr. T. M. Legge, medical inspector of factories, to aid manufacturers, foremen, workers, and others, in recognising the early appearance of anthrax and to impress on them the importance of prompt treatment. Dr. Legge is to be congratulated on having produced such an excellent aid for the prompt recognition of this serious disease and if the placard is framed and posted in some prominent place in workshops where the nature of the business exposes workmen to anthrax it should have the effect of preventing fatal consequences by causing them to seek early and effective medical treatment.

A. B. (Lytham).—There is nothing about the condition which would offer any difficulty to our correspondent's medical attendant.

R. D. P. will be glad to know of any authoritative literature on the diet of Eastern races.

ERRATUM.—In the paragraph headed "Medical Barri ters" on p. 1865 of THE LANCET of June 30th the medical degree of Dr. John Stokes of Sheffield should be M.D. Durh.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), Middlesex (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynaecological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopaedic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (3 P.M.).

TUESDAY (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.).

WEDNESDAY (18th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopaedic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopaedic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.).

THURSDAY (19th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynaecological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopaedic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.).

FRIDAY (20th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopaedic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), St. Mark's (2.30 P.M.).

SATURDAY (11th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &C.

MONDAY (16th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.)—4 P.M.: Dr. J. H. Sequeira: Clinique. (Skin) 5.15 P.M.: Lecture:—Dr. J. M. H. MacLeod: The Treatment of Psoriasis.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—2 P.M.: Medical and Surgical Clinics. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Mr. Dunn: Diseases of the Eye.

TUESDAY (17th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.)—4 P.M.: Dr. L. Guthrie: Clinique. (Medical.) 5.15 P.M.: Lecture:—Dr. C. O. Hawthorne: Pulse Tracings and their Clinical Significance.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—10.30 A.M.: Dr. Moullin: Gynaecological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball and Dr. Davis: Throat, Nose, and Ear Department. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.)—3.30 P.M.: Clinical Lecture:—Dr. J. Collier: Congenital Cerebellar Ataxy.

WEDNESDAY (18th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.)—4 P.M.: Mr. J. Clarke: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Dr. P. Stewart: Recurrent and Transient Palsies.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—10 A.M.: Dr. Ball and Dr. Davis: Throat, Nose, and Ear Department. Dr. Saunders: Diseases of Children. 2 P.M.: Medical and Surgical Clinics. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Dr. Robinson: Diseases of Women.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.)—5 P.M.: Demonstration:—Mr. O. Nourse: Nasal Accessory Sinuses.

THURSDAY (19th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.)—4 P.M.: Mr. Hutcheson: Clinique. (Surgical.) 5.15 P.M.: Lecture:—Mr. T. Walker: On the Methods of Estimating the Function of the Kidneys.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—2 P.M.: Medical and Surgical Clinics. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Mr. Dunn: Diseases of the Eye.

HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.)—4 P.M.: Lecture:—Mr. Fairbank: Some Surgical Affections of the Mouth in Children.

FRIDAY (20th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery-street, W.C.)—4 P.M.: Mr. M. Yearsley: Clinique. (Ear.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—10.30 A.M.: Dr. Moullin: Gynaecological Operations. 2 P.M.: Medical and Surgical Clinics. Dr. Ball and Dr. Davis: Throat, Nose, and Ear Department. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Dr. Abraham: Diseases of the Skin.

SATURDAY (21st).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—10 A.M.: Dr. Ball and Dr. Davis: Throat, Nose, and Ear Department. 2 P.M.: Medical and Surgical Clinics. 2.15 P.M.: X Rays. 2.30 P.M.: Operations. Dr. Robinson: Diseases of Women.

EDITORIAL NOTICES.

It is most important that communications relating to the editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Manager."

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol. I. of 1906, which was completed with the issue of June 30th, and the Title-page to the Volume, were given in THE LANCET of July 7th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1906 will be ready shortly. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.O., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 18 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.O.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An Address

ON

NOTIFICATION OF PULMONARY PHTHISIS.

Delivered at the Forty-eighth Annual Meeting of the Forfarshire Medical Association in University College, Dundee, on June 25th, 1906.

By ROBERT SINCLAIR, M.D. GLASG.,
LL.D. ST. AND.,

CONSULTING PHYSICIAN TO THE DUNDEE ROYAL INFIRMARY;
PRESIDENT OF THE ASSOCIATION.

GENTLEMEN,—When Pasteur finally disposed of the oxygen theory of fermentation and placed the vitalistic theory of that process on the basis of demonstrated fact he went a long way in the direction of verifying the remarkable prophecy of Boyle two hundred years earlier. "The man," said Boyle, "who shall probe to the bottom the nature of ferments and of fermentations will doubtless be much more capable than any other of giving a true explanation of the divers morbid phenomena both of fevers as well as of other affections." Pasteur's masterly researches in the morphology and physiology of micro-organisms laid the foundation of that science of bacteriology which enabled Lister a few years later to rescue the treatment of wounds from a disastrous empiricism and to replace it by a method at once scientific and beneficent, and enabled Koch, after a generation, to make his brilliant discovery of the tubercle bacillus and to end the long-standing controversies as to the nature of pulmonary phthisis and those other tuberculous diseases which we now know to have a common origin. It is the merest truism to say that Pasteur, the French chemist, Lister, the British surgeon, and Koch, the German pathologist, will rank for all time among the foremost men of science and the most honoured benefactors of mankind.

Since Koch's discovery the medical profession and the public have not been idle in their efforts to check the spread of tuberculous disease and to help the recovery of its victims. These efforts are too well known to need repetition now. But before entering on questions which will afford opportunities for difference of opinion and discussion, it may be well to clear the air by a brief summary of the points on which we may be fairly presumed to agree. Tuberculosis is the most fatal of all the diseases of man and the domestic animals; it is most prevalent during adolescent and adult life; it is therefore very costly in loss of life and working power in the most productive years and those most important for the welfare of families and communities. It finds its favourite abode amid poverty, overcrowding, want of cleanliness, air, and light. It is communicable, and the chief mode of infection is the inhalation of dust containing the dried secretions of pulmonary and laryngeal tuberculosis. It is not conveyed from the breath or perspiration. There is no satisfactory proof of the multiplication of the germs outside the body. No direct germicide has yet been found which we can use without the certainty of doing infinitely more harm to the lung tissue than to the bacillus. The last fifty years, which witnessed enormous improvements in general sanitation, have been accompanied by a steady reduction in the mortality from pulmonary phthisis, even apart from special efforts directed to its prevention. All of us are at one in desiring to check its ravages still further.

Now I think we may safely venture on the sea of controversy. Many meetings and congresses have been held, some of them of prodigious length, and have expressed themselves for and against notification. Some medical officers of health are in favour of voluntary and some of compulsory notification. In 1902 a Committee of the House of Commons expressed approval of compulsory notification but not of local enactments. A year ago the Scottish Local Government Board issued a schedule of inquiry on the "administrative control of pulmonary phthisis" with the object of ascertaining the practice of local authorities. Briefly put, the result of the inquiry was that "in no locality have the local authority adequately developed the special organisation necessary for the full administrative control of the disease." In March of this year the Board issued another circular with the view, as it was said, of assisting local authorities in Scotland "in developing and completing their administrative

machinery." This circular goes straight to the point by declaring that "pulmonary phthisis is an infectious disease within the meaning of the Public Health (Scotland) Act, 1897," and after a great deal of excellent advice it goes on to say that for the effective application of the Public Health Act to pulmonary phthisis a system of notification is essential but that "unless it is to be followed by effective measures for the curative treatment of the patients and for prevention of the spread of infection the Board will not feel justified in approving of the compulsory notification of cases of the disease." In the last sentence there is the true ring of the practical administrator and I am sure that the Board has only one object in view—the public welfare—and has no desire to encourage local authorities in the exercise of arbitrary power. Still, one may be allowed to express regret that phthisis has not been dealt with apart from the Notification Act of 1889 and the Public Health Act of 1897, for it requires only a moment's reflection to convince anyone that fevers of short duration and high intensity of infection, for which these Acts were manifestly intended, are by no means on all fours with phthisis, in which the conditions are exactly reversed. Every case of fever is a menace to the public health but a great many cases of phthisis are not. Someone has said very truly that "the consumptive is not a danger in himself, but only becomes so from bad habits." Yet local authorities are now endowed with the same powers in both cases, including the right of entry into suspected houses. Notification is therefore in the air and this must be my apology for bringing the subject before you to-day and for telling you many things which you already know. Stripped of verbiage the problem can be stated in four words—sputum and its disposal. Patients are dangerous to themselves and others only when they neglect timely disinfection or destruction of this secretion in the early stages and when their friends neglect it for them in the later stages. There are thousands of consumptives in private life and in hospitals and sanatoriums who are absolutely innocent of infective power for the simple reason that they practise regularly a few plain rules of personal and domestic cleanliness which may be learned in a few minutes. What is wanted is to induce the uninitiated to enter the ranks of the initiated and until they do so to devise some means whereby the local authorities can guide and direct them for their own advantage and that of their neighbours with the least possible sacrifice of personal liberty. But before the medical officer of health can look after them he must know where they are. How is this to be accomplished? Obviously by some means of notification; and ought this to be voluntary or compulsory?

Here I should like to interpose a word in deprecation of the zeal of two classes of reformers, many of them no doubt the very salt of the earth, whose intervention has not been always helpful. One class regards every consumptive as a danger to his fellows. In addition to his terrible load of suffering and the prospect of an early death he is to be treated as an outcast. A glass spittoon "may be conveniently attached to the person," in imitation, I suppose, of the clapper of the mediæval leper. He is to have a card bearing his name, address, and the date of notification, and if the system is not to be a farce he will require to have his movements recorded on it as if he were a convict on a ticket-of-leave. He is to live apart from ordinary domestic and social life and every obstacle is to be placed in the way of his getting honest employment. Hear a London physician on the subject: "Every man, woman, and child who is tubercular should at once be removed from all possibility of contact, direct and indirect, with the healthy community." Now hear an Edinburgh physician: "Many of these affected cases are at work fatally infecting their fellow workmen as our medical case-books frequently prove." What marvellous case-books! Another enthusiast contributes draft regulations, one of which reads: "Prohibition of patients with actual phthisis [by implication he excludes imaginary phthisis] from frequenting churches, theatres, railway carriages, trams, or any public places." Strange to say, the clergy appear to have endured in silence this new excuse for non-church-going. The typical representative of the other class is intense. He lives the strenuous life; he is convinced that victory is delayed solely because the stalwarts, whose motto is "Thorough," are not allowed to have it all their own way, and he talks knowingly of stamping out tuberculosis as if he were dealing with a sporadic outbreak of typhus or a handful of burning tow.

How do things actually stand in this matter-of-fact world? The conditions in which tuberculosis is most prevalent are

improving steadily but the ending of them under any human system is not yet in sight. The practice is not sufficiently general of offering disinfection of rooms and houses after notice of death has been received, or ought to have been received, from the registrars. The hose and the broom are too little used on our pavements, closes, back courts, and yards. The time-honoured custom of sweeping the street dust over the wayfarers and into the houses of those who live up to the standard of open windows still clings to nearly every part of the kingdom and the watering cart is seldom seen in the land save as the herald of coming rain. The protection of meat from contamination on its way from the abattoir to the shop and from the shop to the consumer, and the supervision of the collection and distribution of milk, still leave much to be desired and are questions well worthy of the attention of those placed in authority over us. Municipal milk depôts, of which we have one excellent example in Dundee, do admirable work in providing a number of children with good milk and thus promote a thoroughly good social object—the physical well-being in early life of a portion of the next generation. But as they are not likely to meet more than a fraction of the demand the question may be fairly raised whether the energy so expended could not be better employed in a more effective control of the whole milk-supply of the district. And of course these depôts are open to the criticism which sound economists apply to all forms of municipal trading—namely, tendencies to extravagance, reactionary methods, want of enterprise, and bureaucracy.

Koch himself, in his Nobel lecture, published in THE LANCET of May 26th last, does not go nearly so far as some of his followers. He calls, it is true, for compulsory notification and other measures against open tuberculosis, but not at all against the closed form, which he regards as "quite harmless." Experience has led to the modification of some optimistic views as to the proportion of recoveries even under the most favourable conditions. We have long known that when all the climatic and hygienic advantages which wealth and leisure can procure are present recovery is slow and not always sure, and in the case of those less favourably situated it is still slower and still less sure. The latter form the class which will always constitute the overwhelming majority of those for whom public health administration is required.

Dr. R. S. Aitchison and Dr. Edward Carmichael have lately presented to the Edinburgh parish council a report showing that over 90 per cent. of the cases of this class under their care at Craiglockhart and Craigleith poorhouses are incurable, and their experience is to a certain extent corroborated by Dr. R. C. Macfie, who gives the results of treatment during his residence at the Sidlaw Sanatorium in THE LANCET of June 16th last (p. 1685) showing that even a small rise in the social conditions above the level of the poorest gives better hopes of recovery. We see constantly around us evidence that the law of inheritance by which the offspring of tuberculous parents are more liable to phthisis than the offspring of the non-tuberculous shows no signs of being abolished yet awhile, that as Dr. W. H. Dickinson happily puts it, "There is the soil as well as the seed," and that the parable of the sower is as true to-day as it was when it was spoken.

The whole case for notification lies in the preventive measures which ought to follow in its wake. On this the advocates of compulsory and the advocates of voluntary notification are agreed. Here they part. Those who favour the long reach of the secular arm hold that compulsion and efficiency will surely go together. They believe anything less than compulsory notification to be a makeshift and a sham, and they think no time ought to be lost in securing a system national, uniform, complete, and foreordained to success. The disciples of voluntarism, on the other hand, remind us that compulsion has often brought its friends into strange and unexpected dilemmas which have led too late to the sorrowful conclusion that it is the first step that counts. They think it best to proceed cautiously, and they prefer to seek the coöperation of the patients and their friends in what is often a long-drawn-out business rather than to irritate them by coercive measures. They would give voluntary notification a fair chance. They point out that it presents no administrative difficulties and that it has worked well in several large English municipalities, and they are perhaps not far wrong in the belief that it will give local authorities quite enough to do for the present, while the public craving for sanitary improvements, coupled with a

possible increase of rates, will be amply satisfied for some time to come. Finally, it may be well to remember that Sheffield is the only town which has so far got compulsory notification, and that for a period of five years, and that Dr. J. Robertson, the late medical officer of health there, now of Birmingham, has put the following opinion on record: "I should strongly deprecate powers being given to any sanitary authority who had not first acquired the machinery and experience derived from a system of voluntary notification."

You are aware that in the circular of March 10th last already alluded to it is left to each local authority to organise the plan considered most appropriate to local conditions, and I must say at once that the scheme recently submitted to the public health committee of the Dundee town council by Dr. Charles Templeman, our excellent medical officer of health, appears to me to be sound, practical, well adapted to our local requirements, and likely to go a long way towards mitigating the evils which we have been considering. His recommendations are threefold: (1) voluntary notification; (2) a central dispensary; and (3) provision for the isolation of advanced cases. With voluntary notification we have already dealt at sufficient length. A municipal dispensary with the medical officer of health at its head and coördinated with the admirable out-patient departments of the Dundee Royal Infirmary and the parish council would be a great step forward. It would be the centre from which patients could be guided as to their habits and mode of life, the depôt for the supply of medicines, sputum flasks, disinfectants, and Japanese paper handkerchiefs to the necessitous poor. It would be also the headquarters for the supervision of patients and for investigation of the conditions in which phthisis arises and recurs in houses and localities. For the idea of the municipal dispensary the world is indebted to Dr. R. W. Phillip of Edinburgh. He organised the first dispensary of the kind in Edinburgh, a voluntary one, 20 years ago and he has worked it since then with conspicuous success. We are glad to have him with us to-day as our guest and we hope he may be long spared to continue the efforts which have already borne so much fruit. Mr. Buist's last official act, before retiring from the chairmanship of our infirmary board, was to express approval of Dr. Templeman's scheme and the desire of those connected with the infirmary to coöperate in carrying it out. In this beneficent coöperation his successor, Mr. Guthrie, and his fellow directors will not be found wanting. The isolation of patients who are in an advanced stage of the disease and whose homes are unsuitable would be a very obvious advantage to all concerned, patients, relatives, neighbours, and the community in which they live. To say nothing of the humanitarian aspect of the question, which is sufficiently clear to everyone, segregation will notably reduce the amount of infective material in any locality, and will therefore commend itself to the prudent, just as fire insurance companies desire the removal of as much combustible material as possible from the premises and the neighbourhoods in which they are financially concerned. Should the town council of Dundee decide on the adoption of Dr. Templeman's scheme I am sure we wish them all success and we can promise them that cordial coöperation which the medical profession has always most willingly extended to sanitary reform.

SCARLET FEVER.—Scarlet fever is still prevalent in many parts of the district round Manchester. At Hyde, some days since, there were 85 cases in the infectious hospital, the largest number on record. At Sandbach in Cheshire its spread is attributed to "gossiping mothers," a cause, it is to be feared, very difficult to remove. The medical officer of health of Gorton, Mr. A. W. Martin, has expressed the opinion that hospital isolation accomplishes very little and is not worth the tremendous expense involved. In his annual report he says that the hospital charges for the past year for scarlet fever amounted to £68. If, as in neighbouring townships, 80 per cent. of the patients had been removed to the hospital the bill would have been £1360. The council has acted on these views for 12 years, with the saving of more than £15,000 to the ratepayers, and, in Mr. Martin's opinion, "at the same time keeping a lower death-rate and a lower infection-rate from the disease as compared with similar districts removing a large percentage of their cases." This certainly speaks well for what may be called the medical discipline of Gorton.

ON THE X RAY SHADOWS OF CYSTIC AND XANTHIC OXIDE CALCULI.

By HENRY MORRIS, M.A., M.B. LOND.,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND;
CONSULTING SURGEON TO THE MIDDLESEX HOSPITAL.

THERE seems to be a pretty general, though erroneous, impression that cystin and xanthin calculi give no shadow by the Roentgen test and that the x rays are therefore no aid in diagnosis where a calculus of either of these substances is present in the urinary tract.

Recently I was asked by a well-known physician to see in consultation a young woman who was passing large quantities of cystin in her urine and whose symptoms pointed to the presence of renal calculus in one or other or both organs. Cystin had been passed in the urine of this patient for a long time and I was given to understand that one of her sisters had for five years at least been passing quantities of the same material and that the father of these young women had for a long period excreted cystin in his urine and was believed to have a renal calculus. I asked if a skiagram had been taken of the patient I had been called on to see, and the reply was that cystin calculi

that of a pin's head to that of a pea, which had been voided at different times by a man, 40 years of age; and eight of the specimens had been obtained from human urinary bladders, six of these having been removed by operation during life. There is also in the Museum of the Royal College of Surgeons an admirable skiagram of one of these specimens taken before its removal by operation from the bladder of a boy, aged seven years. This specimen is marked "D 8" in the catalogue and consists of one-half of a large calculus which, together with the skiagram, was presented to the Museum by Mr. John Murray. The skiagram of the other half of this calculus, which is in the Museum of the Middlesex Hospital, is shown in Fig. 5 accompanying this paper. To settle the question as to whether the depth of this shadow was in any way due to the presence of phosphates Mr. S. G. Shattock was good enough to have an analysis of the calculus made by Dr. H. R. Le Sueur, who reported that it consisted almost entirely of cystin with the admixture of only 0.4 per cent. of inorganic residue, a very minute portion of which is iron.

Fig. 6 shows the shadow of a cystic oxide stone removed by Mr. N. O. McNamara by median lithotomy from a boy, aged two years and eight months. It was analysed at the time by Dr. Dupré who could detect nothing in its composition but cystin.

Fig. 4 shows the shadow of a calculus removed from the kidney of a patient by Mr. W. H. A. Jacobson. No analysis

1. Oxalate of lime. 2. Cystin with phosphate of lime. 3. Cystin with phosphate of lime. 4. Cystin, D 9.

did not give a shadow and that this statement was made on the authority of an able pathologist at a well-known medical school. Recalling the fact related in an early paper on the shadows given by calculi, which I contributed some years ago to THE LANCET,¹ that a gall-stone gives a very faint shadow, probably due to the earthy phosphates and other lime salts, aided possibly by the traces of copper, iron, and manganese mixed with the cholestearine and found in nearly all gall-stones, I doubted the correctness of the authority.

Many cystin calculi contain phosphates of lime as well as traces of phosphates of magnesium and ammonium, but what is much more to the point, sulphur is present in all of them to the extent of 25.53 or 25.81 per cent. It was therefore *a priori* improbable that cystic oxide calculi could fail to give a very deep shadow and I at once took steps to ascertain what really was the result.

In the Museum of the Royal College of Surgeons of England I found 11 examples of cystic oxide calculi; one of them had been removed from the urethra; one from the kidney; one was a series of small calculi, varying in size from

of its composition is, so far as I know, recorded, but it has all the characters of a stone composed exclusively of cystin. It must be well-nigh a unique specimen of a cystin renal calculus removed by operation. The specimen marked "D 6" in the catalogue of the College Museum is a large cystin calculus weighing 1050 grains, removed by Mr. Reginald Harrison from a young man, aged 21 years. It was analysed by Professor Campbell Brown and reported by him to consist of cystin with a small quantity of ammonio-magnesium phosphate and a trace of calcium phosphate.

Fusible calculeous matter covers some cystin and xanthin stones and oxalate of lime is sometimes mixed up in their substance. (See Figs. 2 and 3.) In the specimen marked "D. G. 1" from a youth, aged 19 years, there is seen a layer of calcium oxalate around the entire circumference of the stone at a distance of from one-sixth to one-third of an inch from its outer surface.

From the young woman whose case has given rise to these remarks, Mr. C. R. O. Lyster, the able electro-therapeutist of the Middlesex Hospital, obtained very marked shadows of a calculus in each kidney, but I am not aware of the verification of the composition of these calculi, nor even as to whether or not they have yet been removed from the patient.

¹ THE LANCET, Nov. 14th, 1896.

There are only four examples of xanthin calculi in the Museum of the Royal College of Surgeons. Three of them were removed, presumably, from urinary bladders; two of

5. Cystin. Mr. Murray's specimen. 6. Cystin, D 8.
7. Xanthin.

The shadow of a uric acid calculus to show the slight intensity of shadow as compared with the shadows of cystin and xanthin.

them certainly were from the bladders of Mussulman boys of four and five years of age respectively. The fourth xanthin stone was extracted per anum from a recto-vaginal fistula of a woman, aged 56 years, who had also a vesico-

vaginal fistula, both fistulae having followed a confinement 12 years before the extraction of the stone.

I am indebted to Mr. Lyster for the photographs from which the accompanying illustrations are taken. Figs. 4, 6, and 7 are of specimens in the Hunterian Museum; Figs. 1, 2, 3, 5, and 8 are of specimens in the Middlesex Hospital Museum.

In talking with Dr. J. Mackenzie Davidson since these photographs were taken, on the subject of the shadows of cystin and xanthin, Dr. Davidson drew my attention to a recent paper of his own in which he gives illustrations of the shadows of two small cystin stones and remarks, "Even a cystic oxide calculus is fairly opaque owing to the sulphur atom weighing 32 in it."

Cavendish-square, W.

SOME SOCIAL FACTORS IN THE CAUSATION OF INFANTILE MORTALITY.¹

BY THOMAS DIVINE, M.B., C.M. GLASG.,
D.P.H. R.C.P.S. LOND., D.P.H. CANTAB.,
LATE ASSISTANT MEDICAL OFFICER OF HEALTH OF THE
COUNTY BOROUGH OF HUDDERSFIELD.

It is proposed to discuss, as factors in the causation of infantile mortality, the industrial employment of married women, overcrowding, and high birth-rate. These factors will first be briefly considered separately, the object being to establish that each tends to a high rate of infantile mortality. Thereafter the effect of these three factors in complex operation will be studied, a method by which it is hoped to clear up certain discrepancies which the individual consideration of each factor discloses.

1. *Industrial employment of married women.*—The industrial employment of married women conduces to the neglect of infants. It is quite exceptional to find a woman who can carry on hard work and nourish her child in the manner nature intended, not to speak of the satisfactory performance of other less direct duties involved in the care and attention which the well-being of every infant demands. The following occurs in the report on the health of Burnley² for 1903: "Burnley is the largest textile manufacturing town in Europe—that is, it contains more looms for the weaving of cloth than any other town or city, and, as a larger number of women than men are employed in weaving, it follows that many infants are put out to nurse whilst the mothers are engaged in the weaving shed. When infants a few weeks old are thus put out into the hands of unskilful nurses it becomes certain that the food will be at times unsuitable, and the natural requirements of the infant not attended to. A sensible mother's care is necessary for the up-bringing of a healthy child, and this motherly care cannot be obtained where mothers are extensively employed in factories. It need excite no surprise, then, that in manufacturing towns the infantile mortality is large, very much greater than in non-textile towns where mothers usually nurse their own children, and are not compelled to put them out to nurse." Again, "I consider the factory life of mothers and the bad nursing of children to be the principal causes of this high infant mortality; surely Nature intended mothers to suckle their own infants." Greenwood's³ observations in Blackburn lead to the same conclusion. He points out that employment conduces to neglect in different ways, but by far the most important is the absence of the mother from home and from the child, which involves artificial feeding. This, he concludes, may be called involuntary neglect, for in the main it is so, but it is sometimes deliberately increased. Reid⁴ inquired into the mortality of children under one year of age, in three classes of artisan towns in Staffordshire, in relation to the employment of married women in factories. His statistics cover a period of 20 years and only towns of distinctly artisan population were included. In the first class were included towns with many married women engaged in work; the second class included towns with fewer married women engaged in work; and the third class included those towns

¹ Abstract of a thesis for the degree in medicine.

³ Greenwood: Annual Report upon the Health of Blackburn, 1904, p. 27.

⁴ Reid: Brit. Med. Jour., 1901, vol. II., p. 410.

in which practically no married women were engaged in work. The following table shows the infantile mortality of these three classes with the census population of 1901:—

	Class 1. Many women engaged in work.	Class 2. Fewer women engaged in work.	Class 3. Practically no women engaged in work.
Census population 1901.	147,281	198,955	182,864
10 years 1881-90	195	166	152
10 years 1891-1900	211	177	167

This shows a very regular association of high infantile mortality and the industrial employment of married women. The figures are all the more valuable when one has regard to the fact that other general conditions were similar. Of the 15 county boroughs⁵ of England and Wales in which the proportions of occupied females were 40 per cent. or more, Blackburn, Burnley, and Preston are not only the three with the highest percentage of occupied females but also have the highest percentage of married or widowed women employed. Thus at the census of 1901⁶ Blackburn had 37·9 per cent. of its married or widowed females engaged in occupation, Burnley had 33·8 per cent., and Preston 30·5 per cent. These towns are invariably among the large towns with the highest infantile mortality-rates. The averages for the decennium 1893-1902 were: Blackburn, 199; Burnley, 210; and Preston, 232. It may therefore be fairly concluded that, *prima facie*, the industrial employment of married women tends to a high rate of infantile mortality. Nevertheless, if Blackburn be compared with Salford, which has relatively fewer married women employed, their position as regards infantile mortality is reversed:—

Town.	Average infantile mortality, 1893-1902. ⁷	Percentage of married or widowed females employed (census 1901). ⁸
Salford	202	16·6
Blackburn	199	37·9

2. *Overcrowding* only too frequently sums up the factors of poverty, intemperance, crime, and domestic unhygiene. This cannot be better expressed than in the words of the Registrar-General: "The direct consequences of close aggregation are probably as nothing in comparison with its indirect consequences or concomitants. The more crowded a community the greater, speaking generally, is the amount of abject want, of filth, of crime, of drunkenness, and of other excesses; the more keen is the competition, and the more feverish and exhausting the conditions of life. Moreover, and perhaps more than all, it is in these crowded communities that almost all the most dangerous and unhealthy industries are carried on. It is not so much the aggregation itself as these other factors which are associated with aggregation that produce the high mortality of our great towns, or other thickly populated areas." Newsholme¹⁰ has shown that the true density that should be considered is the number of persons to each room, not the number of persons on a given area. The average density of London (1881-90) was 58 persons to an acre; the Peabody Buildings had an average density of 751 persons to an acre. Yet the average infantile mortality of the Peabody Buildings for the nine years 1882-90 was only 139 as compared with 152 for the whole of London. In the Peabody Buildings, however, the average number of persons to each room was only 1·8, which compared favourably with London as a whole. Sir Shirley F. Murphy has shown a very close connexion between overcrowding and infantile mortality. The following table¹¹ is given in the appendix to his

evidence before the Inter-Departmental Committee on Physical Deterioration.

London Infantile Mortality, 1891-1900.

Proportion of total population living more than two in a room in tenements less than five rooms.	Deaths under one year of age, 1891-1900.	Deaths under one year of age per 1000 living 0-1.
Districts with under 10 per cent.	13,533	142
" " 10-15 "	58,208	180
" " 15-20 "	42,158	190
" " 20-25 "	38,521	193
" " 25-30 "	23,219	210
" " 30-35 "	22,580	222
" " over 35 "	16,800	223

The period of time covered is sufficiently long, and the numbers dealt with are sufficiently large, to yield trustworthy results. The nearer one can, so to speak, approach a factor, the more clearly will its tendency be apparent. This analysis gets very close to the factor of overcrowding and the association is almost absolutely regular, amounting, as it does, to a demonstration.

Of the county boroughs¹² of England and Wales the three with the greatest proportion of their population living under overcrowded conditions—the census standard is two persons to a room, anything over that is "overcrowding"—are Gateshead with 34·54 per cent., Newcastle-on-Tyne with 30·47 per cent., and Sunderland with 30·10 per cent. of the total population living under overcrowded conditions. The average infantile mortality of these three towns for the decennium 1893-1902 was: Gateshead, 174; Newcastle, 173; and Sunderland, 175. It may, therefore, fairly be concluded that overcrowding tends to high infantile mortality. If, however, Gateshead be compared with Leicester, which is comparatively free from overcrowding, the position of these towns as regards infantile mortality is reversed. Thus:—

Town.	Infantile mortality, 1893-1902. ¹³	Per cent. total population overcrowded. ¹⁴
Leicester	187	1·05
Gateshead	174	34·54

3. *High birth-rate.*—The birth-rate has to be looked upon as an index of social status. If the marriage-rates and the birth-rates of certain registration districts in London, selected on social grounds, be calculated for the year 1903, on the census population of 1901, the following result is obtained. The infant deaths per 1000 births in 1903 are also shown.¹⁵

Rate per 1000 persons living.	St George's, Hanover-square.	Kensing-ton.	Hackney.	Stepney.	White-chapel.
Marriage-rate ...	21·3	18·4	14·8	15·1	14·4
Birth-rate	17·5	20·3	28·9	32·3	36·3
Infantile mor- tality }	141	145	128	208	194

I attach great importance to what I conceive to be the true relation between the birth-rate and infantile mortality. It is proposed to show that counties and towns in England and Wales, which have birth-rates *higher* than that in England and Wales, as a whole, have, as a rule, infantile mortality-rates which are *higher* than that in England and Wales as a whole; and, conversely, that counties and towns which have *lower* birth-rates have as a rule *lower* rates of infantile mortality. The necessity of having some standard by which to disclose the true relation between the birth-rate and infantile mortality-rate can readily be understood, and

that of England and Wales as a whole is the best that offers. In order to eliminate accidental variations, it is proposed to take for this inquiry the ten years 1893-1902. The following table¹⁶ has reference to the registration counties of England and Wales. The five counties with the lowest average birth-rates and the five with the highest average birth-rates are compared with England and Wales as a whole. The corresponding average infantile mortality is shown.

Registration Counties in England and Wales.

County.	Average birth-rate, 1893-1902.	Average infantile mortality, 1893-1902.
Rutland	23·3	104
Sussex	23·6	116
Westmorland ...	24·0	102
Surrey	24·3	121
Dorset	24·7	101
England and Wales	29·4	152
Northumberland...	32·3	162
South Wales	33·5	163
Staffordshire ...	34·2	169
Monmouthshire ...	34·4	150
Durham	35·6	167

The following table shows a similar analysis of the 33 great towns.¹⁷ The five with the lowest birth-rates and the five with the highest have been selected:—

Town.	Average birth-rate, 1893-1902. ¹⁸	Average infantile mortality, 1893-1902. ¹⁹
Halifax	23·4	148
Huddersfield ...	23·6	146
Brighton	24·9	156
Bradford	25·3	168
Croydon	25·4	141
England and Wales	29·4	152
Salford	34·1	202
Cardiff	35·0	159
Sunderland	35·6	175
West Ham	35·7	169
Gateshead	36·1	174

If the several districts of any large town be analysed this close relation between birth-rate and infantile mortality is even more strikingly demonstrated. The birth-rate and the infantile mortality-rate will both be found to be lower among the well-to-do classes than among the less favoured classes. This has already been shown by the examination of certain districts in London selected on social grounds. For further illustration the towns of Huddersfield and Leeds have been examined and are here set forth. The low-r birth-rates and lower infantile mortality-rates are found associated in the better-class districts and the reverse holds true of the poorer districts.

Huddersfield, 1893-1902.²⁰

	Mean-population.	Birth-rate.	Infantile mortality.
District of Lindley	8,487	20·7	122
Huddersfield	96,175	23·6	146
Central district... ..	24,616	24·2	169

¹⁶ Compiled from Table II., Sixty-Sixth Annual Report of the Registrar-General.

¹⁷ The 33 great towns are: London, Croydon, West Ham, Brighton, Portsmouth, Norwich, Plymouth, Bristol, Wolverhampton, Birmingham, Leicester, Nottingham, Liverpool, Manchester, Salford, Oldham, Bradford, Leeds, Sheffield, Hull, Sunderland, Gateshead, Newcastle-on-Tyne, Derby, Bolton, Birkbehead, Blackburn, Burnley, Preston, Huddersfield, Halifax, Cardiff, and Swansea.

¹⁸ From figures furnished me by Dr. J. F. W. Tatham, General Register Office, London.

¹⁹ From Table III., Registrar-General's Summary, 1903.

²⁰ Calculated from data in the Annual Report on the Health of Huddersfield, 1903.

Leeds, 1903.²¹

	Population middle of 1903.	Birth-rate, 1903.	Infantile mortality, 1903.
District of Chapeltown ...	38,046	24·82	105
City of Leeds	443,559	29·40	153
District of South Leeds ...	34,474	35·62	184

It may, therefore, be concluded that relatively high birth-rates are, as a rule, associated with relatively high rates of infantile mortality. But of the large towns in England and Wales, in 1893-1902, West Ham had a birth-rate of 35·7 whilst that of Blackburn was only 28·8. Their infantile mortality figures are shown in the following table:—

Town.	Infantile mortality, 1893-1902 ²²	Birth-rate, 1893-1902. ²³
Blackburn	199	28·8
West Ham	169	35·7

Having now indicated the tendency of each of these three factors—namely, industrial employment of married women, overcrowding, and a high birth-rate—one is in a position to study them in complex operation. The following table is

Ten Towns with the Highest Average Infantile Mortality, 1893-1902.

Town.	Average infantile mortality, 1893-1902. ²⁴	Percentage of married or widowed females engaged in occupations. ²⁵	Percentage of total population living under overcrowded conditions. ²⁶	Average birth-rate, 1893-1902. ²⁷

²⁶ *Ibid.*, Table XLII.

²⁷ From figures furnished me by Dr. Tatham, of the General Register Office, Somerset House.

made up from the statistics respecting the 33 large towns in England and Wales. The selection is entirely ruled by the average infantile mortality-rates in the decennium 1893-1902. The ten towns with the highest average infantile mortality and the ten towns with the lowest average infantile mortality are shown, together with census data as to the percentage of married or widowed females engaged in occupation and the condition of each town as to overcrowding. The birth-rates in the decennium 1893-1902 are also given.

This is an attempt to measure, as it were, the intensity with which each separate factor acts and I think that it supports my hypothesis "that the position of each town is determined within small limits by the degree to which these three factors operate in any given instance." In other words, that the position of each town on either list is more or less what one would, having regard to the tendency of each factor, expect it to be. A few examples may be pointed out. It will be granted that the closer one town resembles another in one or two of the factors the more apparent will become the effect of the remaining factor or factors. Thus, Blackburn, according to its figures as to married women engaged in occupations, should have a higher infantile mortality than Preston, Burnley, or Salford—the lower birth-rate of Blackburn places it below. Burnley and Salford have about the same degree of overcrowding; the occupied married women figure of the latter should place it far below the former; but the birth-rate of Salford determines their relative positions. Liverpool and Manchester have three factors pretty much in common, yet the lesser degree of overcrowding in the latter, and its slightly lower birth-rate, give it at least as favourable a position in spite of having a larger proportion of married women engaged in occupation. If Leicester be compared with Burnley it is found that both birth-rates are high; but the Leicester figures for married women engaged in occupation, and its condition as to overcrowding, compare favourably with Burnley, and hence their relative positions. The effect of the high birth-rate and overcrowding in Sheffield is sufficient to give it an infantile mortality comparable to Leicester, although the latter has more than twice as many married women engaged in occupation as Sheffield has.

Taking the low mortality towns, it will be seen that Bradford, according to its figure for married women engaged in occupation, and on account of its overcrowding, should have a higher infantile mortality than West Ham; but the birth-rate places it below. Both Swansea and Cardiff, because of their favourable figures for married women engaged in occupation, and position as to overcrowding, should occupy better places than they do. Their birth-rates determine their position. Both Bradford and Halifax have about the same degree of overcrowding, but the more favourable figures for married women occupied and of birth-rate in the latter places it below. Bristol, on account of married women engaged in occupation, and relatively high-birth-rate, should compare unfavourably with Huddersfield as regards infantile mortality; but it is placed below the latter on account of its comparative immunity from overcrowding. The factors generally conspire to place Croydon in its favourable position. If Croydon be compared with Cardiff the effect of the lower birth-rate of the former is well brought out.

Excursions from one list to another all point to the same conclusion, that in the operation of these three factors the infantile mortality for the most part arises. West Ham and Liverpool have birth-rates and overcrowding fairly comparable. The position of West Ham is determined by having a lesser proportion of married women engaged in occupation. Leicester and Bristol are similarly placed both as regards birth-rate and degree of overcrowding. Bristol

	Infantile mortality.	Percentage of married or widowed females engaged in occupations.	Percentage of total population living under overcrowded conditions.	Birth-rate.
High mortality towns	196.9	21.90	6.10	32.5
England and Wales	152.2	13.20	8.20	29.4
Low mortality towns	155.0	12.56	7.02	28.3

owes its more favourable infantile mortality to a less pronounced operation of the remaining factor. Blackburn and Derby have the same birth-rate. The other two factors are in favour of Derby and against Blackburn. The only discrepancy the table discloses is in the position of Preston and Burnley relative to each other. The averages are but an epitome of the teaching of the whole table.

The factors are mutually related to the infantile mortality; where one factor is low another may be high, and according to the separate degree with which these operate so is the infantile mortality determined. The effect of the rural element in the case of England and Wales, as a whole, is to give, as one would expect, a slightly better infantile mortality-rate than that for the low mortality towns.

Huddersfield.

THE INFLUENCE OF AN EXCESSIVE MEAT DIET ON GROWTH AND NUTRITION.

BY D. CHALMERS WATSON, M.D. EDIN., F.R.C.P. EDIN.

IN a paper published in 1905¹ I drew attention to the increase that had taken place in the consumption of animal food in this country in the past 50 years. It was there pointed out that the amount of meat imported into this country had increased from three pounds per head per annum in 1853 to 50 pounds per head per annum in 1903—a very remarkable increase. A consideration of these figures suggests the question, What amount of animal proteid is requisite for the healthy nutrition of normal subjects? The results of Chittenden's recent researches on the amount of proteid requirements in health have clearly shown that in some important respects the teaching of the text-books on diet is erroneous and have shown the necessity of, in the words of a leading writer, reconsidering our conclusions on diet from their foundations. The necessity for such a re-investigation has further been demonstrated by the results of some preliminary observations on diet, investigated from a new standpoint, published by me in 1904-05, which showed that the administration of an excessive meat diet to normal animals was followed by striking histological changes in the thyroid gland. This evidence of structural change in the thyroid gland under a meat diet indicated the advisability of repeating the experiments on a larger scale. Accordingly, I have during the past year made an extensive series of observations on the influence of a meat diet on (a) the growth and general nutrition, and (b) the structure and functions of the organs of a large number of animals. The present paper deals with the former; it gives an account of the clinical results obtained by feeding rats on an exclusive flesh diet and also some comments on the bearing of these results on some clinical phenomena in the human subject. The diets employed were ox-flesh and horse-flesh, with bread and milk as the control diet. The chemical composition of these dietaries was determined by Dr. Andrew Hunter, assistant in the physiological laboratory of the University of Edinburgh, and is elsewhere given in detail.² The essential facts are summarised in the following table.

	Proteid.	Fat.	Carbohydrate.	Salts.
Ox-flesh	49	46	1.5	2.2
Horse-flesh	81	14	1.7	2.4
Bread and milk	18	4	73.1	3.9

Bread and milk is the diet in common use for tame rats and the control diet used in this experiment was found to be admirably adapted for the growth and nutrition of rats of all ages. In connexion with the experimental diets it may be mentioned that under certain conditions—e.g., in the neighbourhood of abattoirs—the diet of wild rats is mainly one of flesh food of different kinds. Some control observations were made on the influence of the two dietaries (horse-flesh and bread and milk) on wild rats. The effects of the diet were studied in animals of different ages as follows: (1) on very young rats newly weaned (three weeks old), the controls being taken from the same litter—25 rats with 19 controls; (2) on young rats, approximately two

¹ Brit. Med. Jour., July 8th, 1905.

² Journal of Physiology, vol. xxxiv., No. 112.

and a half months old—22 rats with 12 controls; and (3) on full-grown adult rats—14 rats with 10 controls. In the investigations special attention was directed to the following points: (a) the effects of the diet on the growth and nutrition of the meat-fed animals; (b) the health of their offspring; and (c) the recuperative power of a normal diet in animals which had deteriorated as a result of the meat feeding.

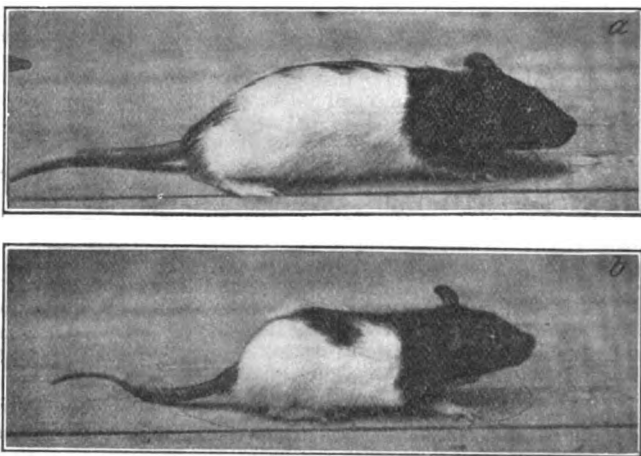

Ox-flesh.—I. *The effect of an ox-flesh diet on very young rats.*—Fourteen young rats from five litters, newly weaned, were placed on an exclusively ox-flesh diet, 11 rats from the same litters being used as controls (bread and skim-milk diet). Five of the meat-fed animals succumbed within four months, their weights and date of death being indicated on Chart 1. The remaining nine animals lived and appeared to thrive, but they gained in weight less than did the controls. Two representative illustrations are given. These show the relative sizes of two male rats of the same litter after being fed for three months on bread and skim milk (Fig. 1a) and ox-flesh (Fig. 1b) respectively.

The general appearance of these nine ox-flesh-fed subjects was in all respects normal; it was, however, observed that some of them moved about in a less lively manner than did normal animals. This lessened activity was associated with, and apparently dependent upon, changes in the osseous system of a rachitic-like nature which were revealed at the post-mortem examination. In the meat-fed animals (litters 4 and 5) four were females, and although kept with males none of them became pregnant, whereas of the three control females from the same litters all bore litters. These results admit of the following conclusions. 1. Very young rats, newly weaned, can in the majority of cases live and thrive on an exclusive ox-flesh diet; their growth is, however,

retarded by this dietary. 2. An ox-flesh diet interferes with the development of pregnancy.

II. *The effect of an ox-flesh diet on young rats from two and a half to three months old.*—Eight rats of an average weight of 65 grammes and approximately two and a half months old

FIG. 1.

To show the relative size of two male rats of the same litter after being fed for three months on bread and skim-milk (a) and ox-flesh (b).

were fed on an exclusively ox-flesh diet, four subjects of similar age and weight being used as controls. The meat-fed animals thrived and were with one exception alive and in apparent health after six months of this feeding. They gained in weight more than the controls (see Chart 2). With the exception of four which became inordinarily fat, all the meat-fed subjects appeared to be in a perfect condition throughout the whole period of observation.

CHART 1.

The influence of an ox-flesh diet on very young rats newly weaned. The dark line equals the average weight of the ox-flesh fed rats. The arrows indicate deaths. The faint line equals the average weight of the control (bread and milk-fed) subjects.

Horse-flesh.—I. *The influence of a diet of horse-flesh on very young rats.*—Eleven animals from five litters were fed on horse-flesh, eight rats from the same litters being used as controls (bread and skim-milk diet). Eight of the 11 meat-fed animals succumbed after a few weeks' diet; the remaining three died within four months. The control subjects lived and thrived. The weight curve of one meat-fed subject is not included in the chart. These results, which are graphically represented in Chart 3, show that a diet of horse-flesh arrests the growth of, and is speedily fatal to, very young rats.

II. *The influence of horse-flesh on young rats approximately two and a half months old.*—Fourteen young rats about two and a half months old were placed on a meat diet, eight control animals of a similar age and weight being fed on bread and skim-milk. Six of the meat-fed subjects succumbed on the third day. On the morning of this day the rats appeared to be in their usual health. An hour after feeding one of them was lying on its side apparently unconscious. In a few minutes others were affected. They appeared to be paralysed. They felt cold to the touch, exhibited symptoms of tetany, and speedily became unconscious. Six succumbed within half an hour. Of the remainder some showed similar symptoms, although in a less degree, and they recovered when the diet was changed to bread and skim-milk. After two days of the normal diet

the remaining rats (five males and three females) were again placed on an exclusively horse-flesh diet. Under this regimen they now gained weight as shown in Chart 4. They exhibited symptoms of deranged nutrition such as accele-

became accustomed to the diet and appeared to thrive on it, but their growth was permanently stunted, the maximum weight of the horse-flesh-fed being distinctly below the control bread and skim-milk-fed subjects. 3. The use of

CHART 2.

The influence of an ox-flesh diet on young rats, the diet being commenced when the animals were between two and three months old. The dark line equals the average of eight ox-flesh-fed rats. The arrow indicates a death. The faint line equals the average of four control (bread and milk-fed) subjects.

rated and noisy respiration with tendency to "pot belly," but these symptoms were in the majority of animals recovered from. The females became pregnant and gave birth to four litters. At the end of the eighth month the animals were alive and in apparent good health, their average weight, however, being below the normal (Chart 4). The results of this observation may be summarised as follows. 1. An exclusive horse-flesh diet was fatal to about 50 per cent. of young rats two and a half months old, death occurring within a few days with symptoms of acute toxic poisoning. 2. In the remaining 50 per cent. the animals

CHART 4.

The influence of a horse-flesh diet on young rats, the diet being commenced when the animals were between two and three months old. The dark line equals the average weight of 14 horse-flesh-fed rats. The arrows indicate deaths. The faint line equals the average weight of eight control (bread and milk-fed) subjects.

this diet in animals of this age appears not to affect the supervention of pregnancy.

III. *The effect of horse-flesh diet on adult rats.*—Nine adult rats of an average weight of 210 grammes were put on an exclusively

horse-flesh diet on March 27th. On this diet their weight was well maintained (see Chart 5). Two succumbed in five months, the remainder being then in fair but by no means perfect condition, the most striking abnormality being the rough condition of the skin. In some cases the rate of respiration was increased, this symptom varying in severity from time to time. The general result of this observation shows that the exclusive horse-flesh diet maintains the body weight of adult rats in the majority of cases (seven out of nine); and also that the general nutrition of the flesh-fed animals was below that of the control bread and skim-milk-fed subjects.

The effects of a meat diet on pregnancy and lactation.—I have already submitted evidence bearing on this subject. It has been shown that when an ox-flesh diet is commenced at a very early period of life pregnancy does not supervene as in animals on a normal diet. Some further points of interest are supplied in the following record of one animal which had four litters in 1905. This animal, on a bread and skim-milk diet, had a litter of nine on April 22nd. This litter lived and thrived. After weaning the mother was transferred to an exclusively horse-flesh diet. Pregnancy supervened and a second litter, also of nine, was born on June 13th. None of the second litter survived longer than two months. The horse-flesh diet was continued and a third litter, six in number, was born on July 30th. These succumbed within one month. The mother was then transferred to the normal bread and skim-milk regimen, and while on this diet a fourth litter, eight in number, was born, all of which lived and thrived. In this and other meat-fed subjects it was

CHART 3.

observed that the mammary glands were less developed than in bread and milk-fed rats.

The influence of a meat diet on the progeny.—The progeny of meat-fed rats are usually poorly developed and show a high mortality in early life. Some statistics on this point are given. Of 93 rats born of meat-fed parents (ox-flesh and horse-flesh) 19 (20 per cent.) were alive at the end of two

three cases (see Chart 6). The improvement in the general condition of the animals was associated with an improvement in the respirations, which became less frequent, less noisy, and with fewer accompaniments. The subject which was originally fed on rice died after five weeks of the new diet; the other two were alive and in fair health in the middle of October. It has to be noted, however, that their average weight in October was 136 grammes, considerably less than the average of a healthy bread and milk-fed subject of the same age. The results of this observation showed that the change of diet to bread and sweet milk in all three subjects was

months, while of 97 rats born of bread and milk-fed rats (84 per cent.) were then alive and in apparent health. The state of development of the progeny of bread and milk-fed rats (Fig. 2a) in comparison with that of meat-fed subjects (Fig. 2b) is illustrated in Fig. 2 for animals six weeks old. The meat fed animal (Fig. 2b) was puny and ill-developed, with scanty hair and dry skin, a picture of general marasmus. It died two weeks after the photograph was taken. One of the 13 meat-fed litters (an ox-flesh litter) was a striking exception to the general rule. When two months old this litter, nine in number, appeared to

FIG. 2.

be in perfect health, their average weight and general appearance being quite up to the normal standard. The high mortality in early life of the second generation of meat-fed rats is probably due in great part to the defective power of lactation in the mothers.

The recuperative power of a normal diet.—Some observations were made on the recuperative power of a normal diet in animals which had deteriorated in consequence of having been fed for some time on an abnormal dietary. The results in the case of flesh-fed animals were in this instance controlled by comparison with those obtained from animals fed on (a) an exclusively rice diet, and (b) an exclusively porridge (made with milk) diet. Observations were made on animals of both the first and second generation.

A. In the first generation.—After the primary observation on each diet had been in progress for five weeks and the natural course of events in each group had been determined, an average representative of the rice-fed, flesh-fed, and porridge-fed animals was taken and put on a diet of bread and sweet milk, the amount of each being unrestricted. This was done on June 4th. At this time the animals showed marked evidence of retarded growth and a considerable degree of respiratory embarrassment. The change of diet was immediately followed by a marked increase in the rate of growth, this being pronounced in all

followed by a rapid and marked improvement in the general condition and also by a marked improvement in respiration. The recovery from the respiratory embarrassment was, however, not complete. It also showed that the growth of the animals had been permanently stunted by the use of the abnormal diet in early life.

With the object of testing the immediate results observed to follow the change of diet another animal was taken from each group and was fed on the control diet of bread and skim-milk. Chart 7 shows the record of weight of these

The influence of a bread and skim-milk diet on young rats previously fed on an abnormal dietary. The curves represent the weight of three young rats that were fed on porridge, rice, and horse-flesh respectively for six weeks and were then (forty-eighth day) transferred to a bread and skim-milk diet.

animals for the period of six weeks during which they were fed on rice, porridge, and horse-flesh diet respectively and thereafter on the control diet. The condition of the rice-fed subject when removed was such that our experience led us to believe that it could not live more than, at the outside,

one or two days longer on that diet. After the change of diet there was a rapid and immediate improvement in the condition of all three animals. The result was even more striking than in the case of the three animals the diet of which had been changed to bread and sweet milk (see chart). All three animals were alive and in fair condition in the middle of October, their average weight at that time (138 grammes) being, however, below the normal.

B. In the second generation.—The recuperative power in the second generation of meat-fed rats was tested in four animals taken from two litters, other four animals from the same litters being employed as controls. After weaning, the eight were kept on a horse-flesh diet for two weeks; in this period their weight was little more than maintained (see Chart 8). Two from each litter were then transferred to a

in their production. There is equally little doubt that among these factors the question of diet occupies a foremost place. The defects in a diet may lie in one of several directions. The food may be of fair nutritive value but insufficient in amount; on the other hand, it may be of high nutritive value, excessive in amount, and of a nature which exercises an injurious effect on the organs and tissues. It is important that some light on this subject should be looked for from experimental medicine, and in view of the increasing prevalence of the consumption of animal food in this country it is of special importance to determine the effects on the organism of an excess of animal proteid food. The main interest of my experimental results lies in the clear evidence submitted that an excessive meat diet can itself induce in animals—whose dietetic habits are fairly akin to those of man—some of the most prominent symptoms of physical deterioration—viz., defective general physique, deficient power of lactation, diminished fertility, and a high infantile mortality. I believe that these symptoms are, to an important extent, comparable to those prevailing in the human subject at the present time, the symptoms in man having, however, been established in a more gradual manner, their onset being contributed to by the operation of other etiological factors.

Some points of practical importance are brought out in the record. Of these the most noteworthy is the importance of a proper dietary in very early life. My experiments showed that the use of an excessive meat régime in early life induced a serious and permanent weakness of the animals, which, however, remained for a long time latent after the substitution of a physiological dietary. Clinical experience has led me to think that we have here also a close parallel in diseases in the human subject, and more especially in the class of affections commonly included under the terms gout and goutiness. Be that as it may, the experimental results indicate the importance of directing particular attention to the early dietetic history of patients so far as these are obtainable. The necessity for this will be further emphasised by the subsequent records of the structural changes in the organs and tissues observed in the course of these experiments.

The experiments referred to in this paper were conducted in the physiological laboratory of the University of Edinburgh with the assistance of grants from the Moray fund of the University and the Carnegie trust, and I take this opportunity of expressing my great indebtedness to Professor Schäfer for invaluable assistance received throughout the investigation.

Edinburgh.

OUTBREAK OF PNEUMONIA IN A REFORMATORY SCHOOL.

BY THOMAS OLIVER, M.A. DURH., M.D., LL.D. GLASC.,
F.R.C.P. LOND.,

PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE.

THE following notes are published in the hope that other physicians drawing their experience from a larger field may be induced to express their views upon some such similar outbreak with which they may have perchance been brought into contact. The outbreak to which I refer occurred fully four years ago. Although at the time I was much interested in the illness I have refrained from publishing the notes of the cases in the hope that some new circumstance might arise which would throw fresh light upon an epidemic of pneumonia that was as sudden in its onset as it was obscure in its causation. I have been informed that outbreaks of pneumonia have recently occurred in other reformatory schools in England and in Scotland, the origin and causation of which are equally mysterious.

Admittedly a microbial disease, pneumonia or pneumonic fever is not a pathological entity due to one and the same micro-organism. The malady owns many causes and yet while an attempt might be made to include under the term pneumonia only the croupous form of the disease, the result of a specific pneumococcus, and to regard all other forms as simply inflammation of the lungs, this would not advance our knowledge, for while the pneumococcus is without doubt the cause of pneumonia there are cases

CHART 8.

Recuperative power in second generation of meat-fed rats. The faint line equals the average weight of four rats bred on an ox-flesh diet which were transferred to a bread and skim-milk diet at the age of six weeks. The dark line equals the average weight of four rats from the same litters which were not transferred but were kept on the meat diet.

bread and skim-milk dietary, the remaining four being kept on the horse flesh diet. All four meat-fed subjects succumbed in two to three weeks, the four transferred rats living and gaining in weight in the striking manner shown on the chart. The later history of these four rats is of great interest. The animals were killed when eight months old, their average weight being 150 grammes. Their health during the later months was very defective, the symptoms manifested being, in order of onset and severity (*a*) accelerated and noisy respirations, dry râles being audible a considerable distance from the hutch and (*b*) a dry condition of the skin with roughness and loss of hair. These clinical features considered alongside of the other facts recorded in this paper point to the general conclusion that the symptoms from which the animals suffered in later life were etiologically related to the use of the defective dietary in very early life. There can, it appears to me, be no reasonable doubt that the symptoms observed were the result of the premature loss of some vital function or functions, and more especially of those concerned in warding off bacterial infection from the respiratory, and probably also the alimentary, tract.

Summary of results.—These experiments prove that the excessive use of a meat diet in rats is attended with the following results: (1) growth is retarded; (2) sterility is induced if the diet is commenced in very early life; (3) the power of lactation is diminished; (4) a permanent weakening of the resisting power of the animals is induced by the use of an excessive meat diet in early life, the animals succumbing to disease at an unusually early age; and (5) there is a high death-rate in the offspring of animals fed on an excessive meat diet.

Concluding remarks.—The facts recorded have an interesting bearing on the two questions of physical deterioration and high infantile mortality that are engaging medical attention at the present time. With regard to these conditions there is no doubt that not one but several factors are concerned

of pneumonia in which this organism is not detected. Asthenic types of the disease are associated with a variety of micro-organisms. Croupous pneumonia, or that due to the pneumococcus of Fränkel, is usually preceded by a rigor, is attended by physical signs pointing to consolidation of lung, runs a definite course, and reaches a crisis within nine days, but it is seldom a disease that becomes epidemic. When it assumes this character it is more than likely that the malady is not due to the pneumococcus alone but to other micro-organisms as well, and therefore the result of a mixed infection.

The industrial school to which I was called by the visiting medical officer is in the neighbourhood of Newcastle-upon-Tyne. It has accommodation for 200 boys and is nearly always full. During the month of April of the particular year in question the only entries in the log-book were one case of Pott's fracture, one case of skin disease, and three cases of abscess. On May 17th two boys, aged 13 years respectively, were seized with pneumonia; five days later (May 22nd) other three boys, also aged about 13 years, were added to the list; ten days later (June 1st) a sixth case occurred in a boy 14 years of age; on June 5th two more cases in boys aged nine and 12 years respectively and on June 23rd the ninth case occurred. This boy, aged 15 years, had complained of headache in the afternoon but so slight did his ailment seem that it was not considered necessary by the governor to summon the medical officer. During the night the nurse, who was attending to some boys in the dormitory, gave him at his own request a drink of milk. A few hours later the lad was found dead in bed. On the following day I made a necropsy. The body was that of a well-nourished boy. Rigor mortis was passing off. There were no signs of external bruising. The pericardium contained a small quantity of free fluid. On the surface of the heart were numerous small petechial hæmorrhages. The heart itself was healthy. There was a small quantity of serous fluid in the left pleural cavity. The base of the left lung was adherent to the diaphragm. On section the lower lobe of the left lung was found to be the seat of the early stage of pneumonia. Beyond being slightly adherent to the diaphragm the right lung presented nothing abnormal. The stomach contained about two ounces of grumous fluid; its mucous membrane as well as that of the intestine was healthy. The liver was large but healthy. The spleen was very much enlarged and pulpy. The kidneys were congested. There were no enlarged glands in the mesentery and no signs of tubercle or of peritonitis. Beyond being paler on its surface than usual the brain presented nothing abnormal. The blood was extremely fluid. The opinion come to by the medical officer and myself was that the boy had died in collapse in the early stage of pneumonia. A bacteriological examination of the blood and fluids was unfortunately not made.

Looking back upon the history of the outbreak it will be observed that in all eight cases of pneumonia occurred between May 18th and June 5th—i.e., in 18 days—and that the ninth, the last and only fatal case, occurred 15 days later. In the expectoration of one of the first two boys who fell ill tubercle bacilli were found in the fourth week, yet this lad not only made a good recovery, but three years after the illness is reported to be quite well and strong and earning his living as a labourer at some iron works. In none of the other cases were tubercle bacilli found. The after-histories of these lads obtained four years subsequently are interesting. The youths are all quite well.

In their clinical aspects the illnesses were ordinary croupous pneumonia. There was nothing unusual or peculiar in the course they ran. In trying to determine the cause of the outbreak we were struck by the fact that most of the cases occurred in one large dormitory in which the sleeping accommodation was overcrowded and the ventilation of the room was defective. The window lighting of this ward, too, was deficient. A new range of windows was put in the blank wall. The other points were at once attended to. Since then not only have there been no fresh cases of pneumonia but the health of the boys has been remarkably good.

I am but giving expression to the opinion of my *confrères* when I say that it is no uncommon thing when pneumonia is prevalent in a town for the disease to break out and to linger in certain streets compared with others. A little while ago I was asked to see in consultation in a neighbouring town several cases of pneumonia in succession within the space of three weeks. Most of the cases occurred in one street in houses not far distant from each other, also in two

or three adjacent streets. Similar outbreaks have occurred in institutions, such as schools, barracks, &c., and not a few of these have been traced to the escape of sewer air into the sleeping rooms. When several cases of pneumonia have thus occurred in close succession there has generally been overcrowding as well.

The fact that death occurred in the case above mentioned within 24 hours of the commencement of the illness rather removes the case from the category of ordinary pneumonia, for in croupous pneumonia it is rare for death to occur before the third or fourth day. Much depends in any case upon the virulence of the microbe and the resistance of the individual. Irritant gases when respired provoke acute bronchial and pulmonary congestion but non-irritant gases are not considered to have any such effect and yet I have found animals die from acute congestion of the lungs after the inhalation of carbon monoxide, which is not usually regarded as an irritant, and men are known to have died from a similar cause, the only gross lesion found after death being acute inflammation of the lungs. What there is in sewer air over and above the gas itself or combination of gases to cause pneumonia we need not discuss. It is for our present purpose enough to know that sewer air can cause pneumonia. Typhoid fever and intestinal toxins from improper food, as in the Middlesbrough epidemic of 1889, are also causes of pneumonia and so too is influenza. There was nothing in the outbreak at the reformatory school to suggest an influenzal origin. The rapidity of development, the crowding of the cases into a brief period of time, and the fact that most of them occurred in one dormitory, all point to the cause or causes having been in the dormitory itself, an opinion confirmed by the disappearance of the malady after the ventilation had been improved and certain structural alterations and rearrangement of the sleeping accommodation had been effected. The condition of the lung found in the boy, accompanied by petechial hæmorrhages on the surface of the heart, recalls some other form of toxæmia than that caused by the pneumococcus, but since under the term pneumonia are included, as already stated, many diseases, not all of them due to one and the same microbe, it is impossible in the present state of our knowledge to do other than include the above under the wide category of pneumonia.

Newcastle-upon-Tyne.

THE RADICAL CURE OF FEMORAL HERNIA.

By ASLETT BALDWIN, F.R.C.S. ENG.,

SENIOR ASSISTANT SURGEON TO THE WEST LONDON HOSPITAL; LECTURER ON PRACTICAL SURGERY AND TEACHER OF OPERATIVE SURGERY AT THE WEST LONDON POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL, HAMMERSMITH-ROAD, W.

FOR some years past I have been practising the following operation for the cure of femoral hernia with, as far as can be ascertained, a uniformly successful result. One of the patients, a woman three months pregnant, had an irreducible rupture; she went to full term. The child is now three and a half years old and there has been no sign of a recurrence of the hernia. I have performed the operation upwards of 20 times; all the cases healed by first intention and caused no trouble whatever.

Method of operation.—A curved incision about one and a half or two inches long is made over the saphenous opening. The sac is isolated and more or less cleared of fat. If not already back the hernia is reduced. A slightly curved hernia director is now introduced up the crural canal in front of the sac and when its point is behind Poupart's ligament it is moved laterally so as for a short distance to strip off the peritoneum from the posterior surface of the transversalis fascia. The point of the director is now pushed farther upwards and tilted forwards so as to make the aponeurosis of the external oblique muscle project about half an inch above Poupart's ligament. A small transverse incision is now made through the aponeurosis, parallel to its fibres, on to the point of the director (Fig. 1), which is now pushed up through the opening. The latter is only just large enough to allow of this being done. A sinus forceps, Spencer Wells forceps, or small nasal polypus forceps—the last, being slightly curved, is more convenient—is now introduced through the opening.

FIG. 1.

An incision being made on to the point of a director which has been passed up the crural canal and its point tilted forwards about half an inch above Poupart's ligament.

FIG. 2.

Sinus forceps passed through the opening above Poupart's ligament, behind the ligament, and through the saphenous opening, and made to grasp the fundus of the sac.

FIG. 3.

The sac pulled out through the opening above Poupart's ligament.

FIG. 4.

Needle threaded as described passed through the neck of the sac, through the opening above Poupart's ligament, across the transverse ramus of the pubes, through the pectineus muscle, and out through the saphenous opening.

FIG. 5.

The sac has been passed back through the opening above Poupart's ligament and rests behind the latter and the transversalis fascia.

FIG. 6.

The two ends of the thread are tied, fixing the sac in its place and obliterating the crural canal.

passed behind Poupart's ligament, and made to project from the saphenous opening; as this is done the director is withdrawn; in its descent it guides the forceps and prevents it from catching. The fundus of the sac is now seized by the forceps (Fig. 2), which is completely withdrawn, dragging the sac out through the opening in the external oblique aponeurosis (Fig. 3). The sac is now pulled out as much as possible and ligatured at the top of its neck. By this manoeuvre no pouch is left in which recurrence may take place. A suture (silk, silkworm gut, and chromicised catgut have been used) is now passed through the fundus of the sac, the suture is drawn through to its middle and then tied, thus leaving two free ends of equal length, or this may be done before the sac is pulled up through the opening in Poupart's ligament, the thread being seized by the forceps and used to pull up the sac. But if the sac is large the thread may tear out and time be lost. One end is now threaded in a strong curved needle, one which will not rotate in the forceps which grasps it. The needle is now passed backwards and forwards through the sac several times, starting at the fundus and finishing at the neck, as described by Macewen for puckering the sac. The needle is now grasped in forceps, or a needle on a handle may be used, and its point is passed through the hole above Poupart's ligament, through the neck of the sac, down to the transverse ramus of the pubes, then by a turn of the wrist the point is made to slide forwards across the pubic bone, as close to it as possible, then to pierce the pectineus muscle and to appear through the inner part of the saphenous opening (Fig. 4). The needle is pulled through, bringing its thread with it. By drawing on the thread and by tucking the sac back again through the hole above Poupart's ligament by means of a stout probe or similar blunt instrument the sac disappears from view and comes to rest in a puckered-up condition behind the transversalis fascia and at the top of the crural canal, which it effectually roofs in. By this time the other end of the thread is hanging out of the hole above Poupart's ligament (Fig. 5). It is tied fairly firmly, but not too tightly, to the thread which projects from the saphenous opening; this fixes the sac in its place and fixes Poupart's ligament to the pectineus muscle, so obliterating the crural canal (Fig. 6). If necessary a second suture may be put in for this purpose but nearer the pubic spine. A suture is now put in to close the hole above Poupart's ligament and the skin incision is closed. Thus there are three distinct checks against the recurrence of the hernia: (1) the sac is ligatured higher up than is possible by the ordinary method and leaves no peritoneal pouch; (2) the sac is used as a buffer or roof above the crural canal; and (3) Poupart's ligament is approximated to the pectineus muscle and obliterates the crural canal.

It may be urged that the sac will slough and cause trouble. This does not take place. It no doubt becomes vascularised, converted into granulation tissue, and ultimately into fibrous tissue. Of course a sepsis is necessary.

In strangulated hernia, where it has appeared safe to leave the sac and where time was precious, I have modified the operation by pushing the sac up through the canal, after having made a little space for it as before, and then sutured Poupart's ligament to the pectineus muscle. The result was perfectly satisfactory; but this method is not such a guarantee against relapse as the former, which I believe to be a genuine radical cure. The operation does not take long and no new or special instruments are required.

Manchester-square, W.

CESSATION OF THE PULSE DURING THE ONSET OF EPILEPTIC FITS,

WITH REMARKS ON THE MECHANISM OF FITS.

BY A. E. RUSSELL, M.D. LOND., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE WEST LONDON HOSPITAL.

THE following case seems worthy of record, inasmuch as it is in accord with other cases which led many years ago to the enunciation of an explanation of the mechanism of epileptic fits which has, however, of late years fallen into discredit.

The patient was a man, aged 21 years. He had suffered from epileptic fits all his life. A maternal aunt had also

been subject to fits all her life. The patient's fits commenced with an aura which was referred to by him as an indescribable sensation in his navel. As he experienced a well-marked aura he was given some capsules of amyl nitrite with instructions to break one and inhale it when he perceived the aura. This he was in time to do on one occasion and affirmed most positively that it warded off the fit. The majority of his fits occurred in bed at night; sometimes in his waking moments. Any emotional excitement was very apt to precipitate a fit. On April 21st he developed a fit in the out-patient room. He uttered a cry and was seen to be rubbing his hands together. His pulse was immediately examined for but was not palpable. He was just commencing the stage of tonic spasm when the wrist was seized. This tonic spasm lasted for about three-quarters of a minute, perhaps a minute. Dr. E. W. Hedley, who examined the other wrist also corroborates the absence of the pulse during the tonic phase. It was not easy to determine exactly when the pulse returned but we feel certain that the pulse did not return until the clonic phase. At first it was feeble but as the fit subsided it became fuller and stronger.

Dr. W. T. Harris of Chiswick has kindly told me of another case which occurred in his practice. A man came to have a tooth extracted. While applying the forceps the patient's head suddenly fell back and his face turned exceedingly pale. On feeling for his pulse Dr. Harris found it to be absent. Thinking that it was a severe syncope attack he attempted to give the patient some sal-volatile but clonic convulsions intervened. These were slight and very transient, consciousness being regained almost immediately. Within a few minutes, however, the patient again turned very pale and became unconscious with tonic spasm. Dr. Harris again noted complete absence of the radial pulse, but at the commencement of the clonic stage a feeble pulse appeared at the wrist which gradually improved as the fit subsided. On questioning the patient he acknowledged having had two previous epileptic fits.

Remarks.—Cessation of the pulse preceding the onset of an epileptic fit has been noticed before. Thus Moxon¹ when examining a patient with cardiac dropsy notes: "I was feeling his pulse carefully; the beats were regular and of moderate strength.....I missed one, then another beat, and then found the pulse to have stopped so entirely that it made me look up suddenly at the man to see what was the matter. His face had become very pale, his head was turned towards his left shoulder, and the lip and cheek were twitching; the spasms then affected his arms, and he passed into a severe epileptic convulsion. At the time when I first noticed the pulse to disappear the man's arm was quite still. I tried to feel the pulse during the convulsion but there was so much muscular movement that I could not distinguish it." On another occasion Moxon was examining the pulse of a man who had been admitted to hospital for uræmic vomiting and convulsions. "I took his wrist and felt his pulse; it was forcible and regular. I was feeling it when it quite disappeared from under my finger, many beats being missed. I looked at him; he had become very pale in the face, twitching set in, and he at once went into a very severe epileptic convulsion." Moxon's house physician, Mr. Lane, corroborated the same fact twice on the same patient. Moxon noted a third example. "I was examining the heart of a young gentleman who was asking my advice on account of attacks of epilepsy. He was standing and I had my stethoscope over his heart and was attending to the quality of the sounds. These sounds stopped suddenly and so completely that in great surprise I moved to look at him and saw him with exceedingly pale face, evidently quite unconscious, his balance just lost and he falling forwards. He forthwith went into severe epileptiform convulsions. Dr. Hughlings Jackson has kindly informed me that he has observed on several occasions the pulse to disappear during the paleness of the face in the onset of attacks of *petit mal*." At the conclusion of his lecture Dr. Southey informed Moxon that in the only instance in which he had his finger on the pulse at the beginning of an epileptic convulsion he observed the pulse to disappear during the onset of the attack. Moxon further remarks that "I have found the pulse present again when the clonic spasms have just commenced." He attributed the cessation of the heart to the action of the pneumogastric nerve but recognised the fact that the cause of this pneumogastric

¹ Moxon: On the Influence of the Circulation on the Nervous System, THE LANCET, April 23rd, 1881, p. 648.

impulse was yet to seek. Hilton Fagge³ records a similar case. He was listening to the heart of an epileptic when it ceased to beat and the man fell back. Presently it recommenced to beat and then there was a little twitching of his hands.

Other similar cases are on record. Hare in his recent work⁴ has revived the old idea that epilepsy is due to cerebral anæmia and has propounded the following statement as representing the sequence of events in the genesis of a fit: "I shall assume provisionally that in epilepsy, as in most of the paroxysmal neuroses, there is a widespread area of vaso-constriction tending to cause a rise in the general blood pressure; that this vaso-constriction whether because it is sudden or because it is very extensive leaves no time or room for adequate compensation by an area of vasodilation; and that consequently cardiac inhibition through the vagus is demanded to check the continuous rise in the general blood pressure so induced. So is occasioned a grave modification of the heart beat of the nature of slowing and weakening, amounting, perhaps, quite often to actual cessation. In this way are produced a more or less sudden fall in the blood pressure and a more or less sudden anæmia of the brain; and this is the proximate factor of the unconsciousness and of the convulsions. Synchronous with the initial rise of blood pressure are the various premonitory symptoms or aura of the fit; synchronous with the sudden fall in blood pressure is the commencement of the unconsciousness and of the tonic muscular spasm; synchronous with the recommencing or accelerating heart beats and the consequent progressive recovery of the blood pressure is the relaxation of the tonic spasm and its substitution by intermittent or clonic convulsions presenting progressively widening intervals. As the blood pressure continues to rise the clonic convulsions become less and less frequent and finally cease."

It is perfectly true that such cardiac arrest is not a constant phenomenon in epilepsy. It is well known that the pulse may be maintained in fair volume throughout the whole fit and Gowers⁴ states: "The pulse may be feeble at the onset but I have never noted an actual initial failure. It is generally unaffected at the commencement. A tracing published by Voisin shows that the heart's action may be perfectly normal during the stage of aura." But it is very possible that cardiac arrest in the onset of an epileptic fit may be much commoner than is suspected. It is obviously a matter of some difficulty to make observations as it is usually impossible to predict when a fit is likely to occur.

The phenomenon merits greater consideration than it has received. It is clear that cardiac arrest may precede the development of the fit and it is also well known that stoppage of the heart for a sufficient period will give rise to attacks of unconsciousness and convulsions, the so-called Stokes-Adams syndrome. A most remarkable case has been published by Webster,⁵ of a man, aged 48 years, whose heart would intermit for periods varying from 10 to 20 seconds. The features observed in one of these periods of intermission were that so soon as the pulse became suspended the face became rapidly and extremely pale; later, after some 15 seconds of absence of pulse spasmodic twitchings of the muscles of the face were observed; as the period lengthened still further the spasmodic movements extended to the muscles of the neck and ultimately the arms and legs took part in the convulsive movements. During the more severe crises either concomitant squint of both eyes or conjugate deviation to either side was observed and the pupils became widely dilated. Respiration was noisy, with considerable puffing out of the cheeks, and froth appeared at the mouth. During the greater part of the period the patient was quite unconscious. Flushing of the face and return of consciousness were always almost simultaneous with the appearance of the pulse at the radial artery, the pulse being felt slightly before the flushing of the face was observed. Webster's paper is accompanied by a series of 60 beautiful sphygmograms which establish beyond question that the arrest of the heart preceded the epileptiform attack. Another very instructive case has been published by J. M. Finny.⁶

The efficacy of cerebral anæmia as a means of producing unconsciousness and convulsions scarcely requires mention. The well-known experiments of Kussmaul and Tenner and the effects of a rapid and severe hæmorrhage in man may be just mentioned. No cause could be more potent than a sudden cessation of the beating of the heart for the production of an anæmia not only of the brain but of the medulla, cord, and entire body. It would account for the unconsciousness and it is beyond dispute that it can produce convulsions; it would act as the "physiological fulminate" of Hughlings Jackson.

Sudden cessation of the heart can certainly cause tonic spasm, as recorded in a case of sudden death due to vagus inhibition of the heart reported by me.⁷ The clonic spasms are more difficult of explanation. According to Hare they may be due to the return of the blood to the brain and in this connexion a case reported by W. Broadbent⁸ is worthy of note. The patient was a woman, aged 44 years, with double mitral disease, who for seven years had been subject to epileptic fits. One evening "she was sitting talking to her daughter when she was suddenly unable to speak plainly and became rigid preparatory to a fit. Her daughter stated that instead of the usual fit there was irregular jerking of the right arm and leg and the mouth was drawn over to the right, but she says the head was turned to the left; the left arm and the left leg remained absolutely passive. She passed water during the fit." She was unconscious for five hours after the fit and was then found to have left hemiplegia and hemianæsthesia. Death occurred on the ninth day. Post mortem, in the right middle cerebral artery just beyond the point of origin a small embolus was found with a distal thrombus for half an inch. There was extreme softening both of the cortex and of the basal ganglia of the right side of the brain.

The case is recorded as one of cerebral embolism occurring just at the commencement of an epileptic fit; but whether that was so or whether the embolus initiated the attack is difficult of proof. Cerebral embolism is not infrequently associated with convulsions and occurring in an epileptic fit would presumably be still more likely to precipitate a fit. If in this particular patient the fits were associated with cardiac arrest, the extremely interesting point arises that the embolus would prevent any return of blood to the right side of the brain. The case therefore affords support to the theory that the clonic convulsions are due to the returning blood flow.

The fact that a powerful mechanism for producing cardiac inhibition does exist in the vagus nerve and in its connexions would be sufficient to account for the cardiac arrest that occurs in certain cases of epilepsy. If such mechanism were unduly sensitive or if the ordinary causes which induce vagus inhibition of the heart (such as a rise in blood pressure) were either abnormal or excessive, then cardiac inhibition might occur with undue ease and frequency. It might be urged that stoppage of the heart is a serious event and that if it occurred frequently there would be some probability of its bringing about the death of the patient. But it is a fundamental physiological fact that under experimental stimulation of the vagus there is a practically irresistible tendency for the heart to recommence beating, even during the stimulation—the so-called vagus escape of the heart. This vagus escape of the heart would account for the recovery from the fits. It is not contended that vagus inhibition of the heart occurs as an initial factor in every epileptic fit. Any cause competent to produce a sudden or rapid cerebral anæmia might be equally efficient and in this connexion it may be remembered that vaso-constriction of the cerebral arteries has been advanced in the past as the cause of epilepsy. This hypothesis has been discredited but the recent demonstration of nerve fibres in the cerebral vessels and other evidence of vaso-motor activity in the brain give considerable food for thought.

The phenomena of Raynaud's disease find adequate explanation in extreme vaso-constriction occurring in the affected parts. The cerebral complications which occasionally occur are explicable on the grounds that a similar constriction occurs in the cerebral vessels. Thus Osler⁹ records the case of a woman, aged 48 years, who was subject

to the ordinary phenomena of Raynaud's disease but in addition she had three attacks of aphasia with partial right hemiplegia occurring with the attacks of Raynaud's disease and one of left-sided weakness. These were transient and in each case followed by perfect recovery. That the retinal artery may be narrowed with impairment of vision is also known to occur in Raynaud's disease. Such phenomena strongly favour the view that the cerebral arteries, like those in other situations, are subject to variations in their calibre. It is very interesting, moreover, to note that Raynaud's disease is apt to be associated with epileptic fits and, indeed, *Monro*¹⁰ states that 5 per cent. of cases of Raynaud's disease have suffered from convulsions at some time or other and several very striking cases of the association are on record. *Thomas and Osler*¹¹ record the case of a man whose attacks of Raynaud's disease were associated with severe epileptic attacks. The sequence of events was as follows. Firstly, the fingers became cold, white and dead, and the nails blue, associated with considerable pain. Then followed general chilliness with cold feet. These premonitory symptoms lasted for five minutes and were succeeded by unconsciousness and convulsions lasting for half an hour. In this case there was, firstly, the arterial spasm leading to the local syncope of the fingers; and secondly, general chilliness probably to be attributed to a general cutaneous vaso-constriction. The resulting rise of blood pressure on *Hare's hypothesis* would be the factor determining the vagus inhibition of the heart. The convulsions might also be explained by a vaso-constriction affecting the cerebral vessels, the occurrence of which in cases of Raynaud's disease has been suggested above. Other cases illustrating the association of epilepsy and Raynaud's disease are also on record. *Harvey Cushing*¹² notes that, "contrary to the positive statements of many, substances like epinephrin will blanch the pial vessels over the area of its application, as will occasionally a jet of cold water against the brain or the faradic current used for cortical stimulation."

This short paper has been written to point out that cardiac arrest does occur in some cases of epilepsy and to suggest that such arrest may be far commoner than is suspected. If observations were made on the pulse at the onset of fits by those whose work brings them into contact with epileptic patients in considerable numbers it would soon be established whether such cardiac arrest be of occasional or of frequent occurrence. Sudden cerebral anæmia due to cardiac inhibition (or to cerebral vaso-motor spasm) would account for most of the symptoms of an epileptic fit and it is suggested that the recovery from the fits finds adequate explanation in the well-known physiological fact—the vagus escape of the heart. Certain morbid changes have been described in the brains of epileptics but it is at least possible that they may be secondary to the repeated attacks of transient cerebral anæmia which must follow cardiac arrest and to the extreme congestion of the brain that the convulsive movements give rise to. Even if cardiac arrest can be proved to have no etiological influence in the mechanism of an attack it is worthy of study and is a symptom of great clinical importance, but it would be singular if a condition which in itself is competent to produce an epileptic fit were merely a side issue in the course of an attack.

ST. BARTHOLOMEW'S HOSPITAL AND COLLEGE.—The following scholarships, medals, and prizes have been awarded at St. Bartholomew's Medical School: The Lawrence scholarship and gold medal in medicine, surgery, and midwifery (value £45) to G. C. E. Simpson. The Brackenbury scholarship in medicine (value £39) to P. L. Giuseppe and J. K. Willis (equal). The Brackenbury scholarship in surgery (value £39) to R. H. Bott. The Matthews Duncan prize in midwifery to D. W. Hame. The Burrows prize in pathology to P. L. Giuseppe. The Skyner prize in morbid anatomy in reference to scarlet and rheumatic fevers to E. E. Cockayne. The Willett medal for operative surgery to J. C. Mead. The Wix prize for an essay on the Life and Works of Sir William Savory to K. Macfarlane Walker. The Shuter scholarship in anatomy and physiology (value £50) to H. T. H. Butt of Christ's College, Cambridge

NOTES OF TWO CASES OF AMPUTATION OF THE SHOULDER-GIRDLE.¹

By J. CRAWFORD RENTON, M.D. EDIN.,
SURGEON AND LECTURER ON CLINICAL SURGERY AT THE WESTERN INFIRMARY, GLASGOW; EXAMINER IN SURGERY AND CLINICAL SURGERY IN THE UNIVERSITY OF ABERDEEN.

CASE 1.—The patient, a man, aged 40 years, was sent to me by Dr. A. N. Montgomery and was admitted to the Western Infirmary in December, 1900, suffering from an ulcer over the right forearm. There was a history of syphilis and the patient stated that he had had a nodule on the arm for 14 years. A portion of the ulcer was removed and was found on examination by Dr. A. R. Ferguson to be an epithelioma. His arm was amputated in the middle of the upper arm. In April, 1903, the disease recurred in the stump. The rest of the arm was disarticulated at the shoulder-joint and the growth was then found to look like a spindle-celled sarcoma, which is a point of considerable interest and which will be referred to later. On Feb. 10th, 1906, the patient returned with a recurrence, the whole stump and axilla being occupied by a very large tumour. Removal of the tumour was recommended and on the 19th the clavicle was divided at its inner third, the subclavian artery and vein were tied, and the tumour along with the scapula and two-thirds of the clavicle and an additional growth on the side of the chest were removed. By adopting this method, recommended by Berger, there was practically almost no bleeding, a few intercostal branches being easily secured as they were divided. The patient suffered from very little shock and made an excellent recovery. Stereoscopic photographs showed the condition previously to, and after, operation, as also the appearance of the patient with an artificial arm applied.

Report by Dr. M. LOGAN TAYLOR.—On dissection of the stump, which was removed along with the scapula and the outer half of the clavicle, a large tumour mass is found occupying the original position of the head of the humerus and extending down the axillary border of the scapula to its inferior angle. In this tumour mass are involved practically all the muscles about the shoulder-joint, the deltoid especially being inseparable from it. The cut ends of the axillary vessels and of the brachial plexus of nerves run right into the centre of the growth. Microscopical examination of this second recurrence shows it to be a carcinoma. At first sight it has not got just the typical appearance of a squamous-celled epithelioma, but closer examination of the tumour cells shows them to be undoubtedly epithelial cells of the squamous type. The stroma is very well developed; alveoli are numerous and are filled with epithelial cells which in many instances are undergoing mucoid degeneration.

The primary growth was reported by Dr. Ferguson as being a squamous epithelioma, the first recurrence by Dr. J. H. Teacher (April, 1903) as being a spindle-celled sarcoma, though he was aware at the time of the primary growth being a cancer, and now this second recurrence turns out to be epithelioma. Unfortunately the sections of the previous growths have not been kept, so it is impossible to refer to them now. Dr. Teacher thinks that the first recurrence may have been a cancer after all but closely simulating a sarcoma.

CASE 2.—The patient, a woman, aged 60 years, was sent to me by Dr. M. T. Mackenzie of Scolpaig and was admitted to the Western Infirmary on Feb. 23rd, 1906. Two years ago she had hysterectomy performed for uterine fibroid by Professor Murdoch Cameron. She now suffered from a large tumour involving the upper part of the right humerus which was broken. The circumference of the arm was 14½ inches, as compared with 12 inches on the opposite side. The tumour had extended so much into the axilla and had pushed up the supraclavicular space that anything short of a shoulder girdle amputation was impossible. This was carried out exactly as is above described. There was very little shock and the patient went home on March 19th.

Report by Dr. TAYLOR.—The growth in the humerus is a large one, measuring 6 × 3½ × 3 inches. It extends from the anatomical neck of the humerus to the middle of the shaft. It is now impossible to say whether it has been originally a

¹ A paper read before the Glasgow Pathological and Clinical Society.

central or a periosteal growth for the tumour has completely replaced the shaft in the part affected. The articular surface of the head of the bone is seen at the upper end of the tumour but it is comparatively loose and could be easily torn away from the growth. The distal half of the humerus after removal of all the muscles was found to be attached to the lower end of the growth quite loosely by some tumour tissue. The muscles about the shoulder were adherent to the growth but were involved to a slight degree only. Microscopical examination shows the growth to be a sarcoma of the mixed-cell type, the majority of the cells being small round ones; the others are short spindles.

Remarks.—The two cases above described were operated on within ten days of each other and they illustrate the great value of Berger's amputation. By carrying out his method the mortality is practically the same as amputation at the shoulder-joint, which is extremely small. There was no special difficulty with either operation except in the woman, where it was a little more troublesome to expose the subclavian artery and vein owing to her stoutness and the size of the tumour. I have great pleasure in strongly recommending the operation.

Glasgow.

THE OPERATIVE TREATMENT OF LARYNGEAL PAPILLOMATA IN CHILDREN.

By D. R. PATERSON, M.D. EDIN.,

SURGEON TO THE EAR, NOSE, AND THROAT DEPARTMENT, CARDIFF INFIRMARY.

THE frequency with which papers appear upon this subject is an indication of the difficulties which surround it and of the unsatisfactory nature of the results. Its importance, however, should not be under-estimated as the frequent recurrence of these growths, even after what appears to be complete removal, is a constant menace to the life of the child. Of the three methods of treatment generally practised the operation of thyrotomy has been advocated on the ground that it permits of a more thorough clearance of the larynx. It exposes the parts completely and enables the operator to curette away all the affected tissue. Many objections have, however, been urged against it. Apart from the ordinary risks incidental to external cutting operations on the air passages, which are by no means insignificant, injury to the voice has resulted in not a few instances. Moreover, it does not guard against recurrence, however completely it may be done, and repetition of the operation may be necessary. Many cases are recorded of recurrence after thyrotomy and in one instance this operation was performed on a child as many as 17 times within two years.

Another mode of treatment—the performance of tracheotomy—is often a matter of urgency. Some authorities advise postponing any operation until the patient is older, unless, of course, obstruction of breathing supervenes. Insertion of a cannula in the trachea insures rest to the glottis for a prolonged period and has been followed by good results in many cases. It is necessary, however, to retain the tube for a considerable time, from 18 months to two years, and this cannot be regarded as a measure without some risk. I have on one occasion seen disappearance of the papillomata after a tube had been worn for that period but in others it had to be supplemented by the third or endolaryngeal method. This procedure, which is the one usually adopted by laryngologists, is an attempt to remove the growths by the natural passages. In order to control it, the use of the laryngoscope is necessary but the difficulties with this instrument in young children are so great that it is sometimes impossible even to get a satisfactory view of the larynx. For some years I used this method in the manner generally adopted, with the child under a general anæsthetic combined with local anæsthesia. The little patient, placed sitting in the nurse's lap, has chloroform administered in that position. Several assistants are required. A solution of cocaine brushed on the pharynx and larynx enables the instruments to be used without exciting reflex action, but great difficulty is experienced in keeping the part free from the copious secretion of mucus. I generally employed Mackenzie's spoon-blade forceps and for the smaller pieces Schroeter's instrument which could be moulded to fit into recesses.

This procedure is of course very difficult to carry out in young children and in many cases it is impossible to thoroughly clear the larynx. Still, in a few cases excellent results were obtained, but the difficulty of clearing the anterior commissure and subglottic space is so great that recurrence is frequent and the operation has to be repeated. Some operators abandon the laryngoscope and are content to be guided solely by the sense of touch. Here the patient is placed on the back on a table under a general anæsthetic, but even with guarded instruments this procedure is not without risk of damaging the larynx. I have several times adopted it but have rarely succeeded in effecting a good clearance. Though these difficulties stand in the way of the general adoption of the endolaryngeal method there is no question that it should be tried in the first instance as it involves less risk to life and to the voice. This can be more strongly urged at the present time as the drawbacks I have enumerated are almost entirely got rid of by employing the direct method of examining the larynx. The ease with which the larynx can now be brought under inspection and the excellent view of the field of operation which may be obtained have much simplified endolaryngeal procedure and rendered it more effective. The advantages of this method are great and it is the purpose of this short paper to draw attention to them as illustrated by my own experience.

The introduction in 1895 by Kirstein of the autoscope marked a real advance in the direct examination of the larynx. His "universal spatula" I found very serviceable for inspection of the larynx though the amount of pressure that had to be exerted in order to depress the tongue made it in certain cases difficult to manipulate. To overcome this

Killian employed a tube spatula and this improvement has greatly simplified the procedure and rendered it easier to carry out.

The instruments required for the removal of papillomata by the direct method are a fish-tail tube spatula with handle attached and a straight forceps. The best form of illumination is the Kirstein electric head lamp which has very good illuminating power. The operating table should be of sufficient height to enable the operator when seated on a low chair to work conveniently. If the table be too low he has to assume a cramped uncomfortable position in which the light is uncertain and the instruments are difficult to manage with ease and precision. The patient should be placed on the back with the head hanging over the end of the table and a low pillow under the shoulders. Chloroform is the most suitable anæsthetic to administer and full anæsthesia can be easily kept up from a Junker's inhaler with the mouth-tube hooked round the angle of the mouth. The

pharynx is brushed lightly with a 10 per cent. solution of cocaine, the tube spatula is introduced, and through it the entrance of the larynx and the under surface of the epiglottis are similarly brushed. A few drops of adrenalin may be added to the cocaine solution as it prolongs the anaesthesia and prevents hæmorrhage during the operation. The difficulty with the mucous secretion is comparatively slight in this position as it drains into the most dependent part of the pharynx. Very little chloroform is required to maintain the general anaesthesia, a matter of some comfort to the operator as the expired chloroform coming out in a jet through the tube spatula impinges on his eye, causing smarting and interfering with the proper view of the parts. In the introduction of the spatula its point is passed along the under surface of the epiglottis and then tilted upwards so that it carries that structure forwards and enables an admirable view of the larynx to be obtained. In the majority of cases even this is not necessary. Placing the fish-tail end of the spatula on the base of the tongue immediately in front of the epiglottis and exerting pressure forwards is quite sufficient to bring the interior of the larynx into full view, and the whole of the operation can be carried out with the spatula in that position. For the removal of the papillomata I have employed various forms of forceps and after several trials I have had constructed by Messrs. Mayer and Meltzer one that I find very serviceable (*vide* illustration). It is a forceps with a straight shank fashioned on the crocodile principle and terminating in a beak with cutting edges. From the bend on the shank to the tip the length is nearly eight inches. It is used through the tube spatula and is lightly built so as to interfere with the view as little as possible. At the same time it is capable of dealing with fairly tough tissue. Various forms of beaks have been constructed to fit into the different parts of the larynx.

In operating the forceps is introduced through the spatula and the pieces are grasped and removed. If it is done rapidly the larynx can be fairly cleared before hæmorrhage shows itself to any extent. This is never very prominent and the head being dependent it runs into the pharynx where it can be mopped up. The two parts of the larynx which are most difficult to get at are the anterior commissure and the subglottic space. It is here that recurrence is most apt to take place, as the removal is generally imperfect. In one case the recurrence was eventually limited to the region of the anterior commissure. The beak of the straight forceps can be inserted into this space and a more complete clearance effected. It is more difficult to deal with the subglottic area, as the surface is more flat and the projecting masses are not so easy to grasp. The narrow-beaked forceps have been found very serviceable here and their use may be supplemented by a curette. For this purpose I have employed a modification of Lõri's curette. This instrument has a receptacle to catch the detached pieces of growth and prevent their being aspirated into the air passages and has terminals of different calibre to suit various sizes of larynx. I have had the instrument adapted to the direct method by using a shank similar to that of the forceps. As it cuts from below upwards it is passed beyond the part to be removed and, pressed firmly against the tissue, it is drawn with a firm stroke upwards. As the cutting edge can be adapted to any part of the interior of the larynx any remaining papillomata can be dealt with effectually. As the larynx of the child is capable of considerable lateral displacement it is of much help to have the organ steadied from outside by an assistant. Much greater pressure can then be exerted, notably where the papillomata are sessile and tough. The endolaryngeal operation carried out by the direct method has given such excellent results that I have no hesitation in urging its adoption in the first instance in all cases of laryngeal papillomata. Where recurrence takes place soon and is persistent I would advise in addition the wearing of a tracheotomy tube for a time. This has a distinctly good effect in retarding the growth and enables the operator to deal more thoroughly with the papillomata at each sitting.

Cardiff.

PAIGNTON (DEVON) COTTAGE HOSPITAL.—The committee of the Paignton Cottage Hospital has decided to erect a new operating theatre and to provide extra accommodation for the administrative block. The cost of the undertaking has been estimated at £1172 and the work is to be commenced shortly.

A CASE OF CONGENITAL ABNORMALITY OF THE GENITO-URINARY ORGANS.

By G. F. DARWALL SMITH, M.B., B.Ch. OXON.,
F.R.O.S. ENG.,

OBSTETRIC TUTOR AND REGISTRAR TO ST. GEORGE'S HOSPITAL;
AND

A. LIONEL H. SMITH, M.R.C.S. ENG., L.R.C.P. LOND.,
REGISTRAR TO THE GENERAL LYING-IN HOSPITAL.

THE following case seems sufficiently uncommon to deserve publication.

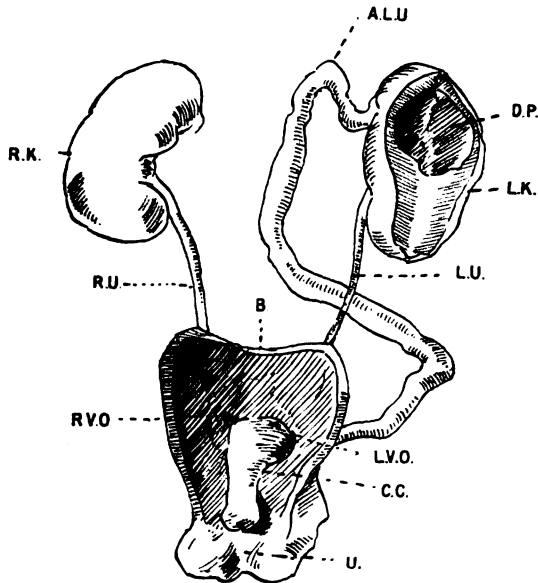

Clinical description.—The patient, a female infant, was first seen by one of us on Oct. 6th, 1905. She was then five days old. Her mother had been attended at her confinement by a very experienced and highly skilled midwife who is an inspector of midwives under the Central Midwives Board. This midwife reported that at birth the child presented no external abnormality and that the labour had been normal in every respect but that on the fourth day the condition immediately to be described was first seen. On the fifth day when seen by one of us this condition was as follows. A dark red globular swelling of the size of a walnut was protruding from the vulva. On its surface were a few darker hæmorrhagic patches and a little blood was oozing from it. The swelling was thoroughly bathed with boric acid lotion and was examined further under full antiseptic precautions. It was then found to be protruding from the urethra. The orifice of the vagina, which appeared quite normal, was posterior to it and behind this again there was slight prolapse of the rectal mucous membrane. The swelling felt cystic and rather thin-walled but was not particularly tense. It did not seem to be tender when handled gently and gave no impulse to the hand when the child cried. On the right side near its base one ureteric orifice could be seen from which a little urine spurted gently at intervals. The left side showed more congestion than the right but no ureteric orifice could be found here, although urine appeared to well up on this side also. The swelling was not at all tightly gripped by the urethral orifice. Several attempts were then made to compress and reduce the swelling back through the urethra with the fingers but as these were unsuccessful a blunt probe was used very gently to push it up by degrees, starting from its base. On one occasion while this was being done, in spite of great gentleness the probe felt as though it had pierced the wall of the swelling; there was, however, no gush of fluid from the puncture (if puncture there was) nor was there any appreciable decrease in size of the protrusion. However, after this the probe was laid aside and replacement was finally effected by passing the whole of the little finger up the urethra, through which the finger passed with extraordinary ease. The reduction did not seem to cause any pain. The child appeared perfectly well and there was no history that she had been ailing in any way. Neither abdominal nor rectal examination disclosed anything abnormal and no cause for straining could be discovered elsewhere.

The diagnosis seemed to lie between inversion of the whole bladder wall, inversion of the mucous membrane of the bladder, and prolapse of a "ureteric cyst," together with part of the bladder. Inversion of the whole bladder wall seemed improbable owing to the apparent thinness of the walls of the swelling and owing to the absence of any impulse on crying, while the absence of any discoverable ureteric orifice on the left side seemed to point to some possible connexion between the swelling and the left ureter. The swelling had not the funnel-shaped appearance which is described as being characteristic of prolapse of the ureter. As the child appeared perfectly well it seemed best to watch the case for the present. Accordingly a pad of aseptic wool was applied to the vulva, cleansing of the vulva with boric acid lotion at frequent intervals was ordered, and dilute boric acid ointment was applied to the skin in the neighbourhood.

It may be mentioned that the child had two elder brothers who were said to be normal in every respect and her parents similarly denied any abnormality of their persons. During the night of Oct. 6th the swelling again came down but was much smaller than before. It was also now rather darker in colour and quite flaccid. There was no sign of any sloughing or infection of its surface. It was replaced as before. During the next 24 hours it was replaced three times but each time that it came down it was smaller than when last seen. The child remained quite happy and well.

On the 8th the swelling only appeared once and was distinctly smaller. It did not appear again until the 10th, when it was only of about the size of a large pea. On the 13th it appeared and was replaced for the last time, and on this occasion it was noticed that the vesical sphincter was distinctly tighter than it had been hitherto. The child throughout seemed very well and contented and between the 8th and 14th had gained six and a half ounces in weight, in spite of a change from the breast to bottle feeding. On the 15th she suddenly had a convulsion during which she died. The cause of the convulsion was not obvious.

Pathological description.—A necropsy was performed about 12 hours after death. Rigor mortis was fairly well marked. Post-mortem hypostatic congestion was present over the most dependent parts. The buttocks were not sore. The hands were tightly clenched and the lips were almost black.

Semi-diagrammatic representation of the parts in a case of congenital abnormality of the genito-urinary organs. B, Bladder. U, Urethra. R.K., Right kidney. R.U., Right ureter. L.V.O., Vesical orifice of left ureter. A.L.U., Accessory left ureter. D.P., Dilated pelvis to left accessory ureter. L.K., Left kidney. L.U., Left ureter. L.V.O., Vesical orifice of left ureter. C.C., Collapsed ureteric cyst.

The general appearance of the cadaver was strongly suggestive of death from asphyxia. The body was rather small but well nourished and the amount of subcutaneous fat was normal. An incision was made in the middle line from the chin to a little above the umbilicus. Thence it was carried slightly on the left to the pubes so as to avoid injury to the urachus.

The thorax: There was no fluid in either pleural cavity. Scattered over the surface of each lung were a few small subpleural hæmorrhages, varying in size from that of a pin's head to that of a millet seed. On section the lungs were found to be normal, except that they were rather engorged. There was no excess of fluid in the pericardium. Scattered over the surface of the heart were a few sub-pericardial hæmorrhages similar to those found on the lungs. In other respects the heart was normal. The thymus seemed rather smaller than usual. The larynx, trachea, and bronchi were normal.

The abdomen: There was no fluid in the peritoneal cavity. The liver was normal. The spleen was rather smaller than usual but was otherwise normal. The pelvic colon entered the pelvis on the right side, its usual situation being occupied by a coiled tube similar in size and appearance to the rectum but obviously having no connexion with the intestine. The ovaries and Fallopian tubes were lying on the dorsal abdominal wall, reaching as high up as, and intimately attached to, the inferior end of either kidney. On the left side of the abdomen beneath the peritoneum was a tortuous tube very similar in size and appearance to the colon, for which it was at first sight mistaken. This, however, on further dissection was found to be a very much dilated accessory ureter. The whole length of the intestine from the stomach to the end of the rectum was removed. It was found to be normal. The pelvis was split through the

symphysis and the two halves were widely separated. The vagina, rectum, bladder, uterus, Fallopian tubes, ovaries, ureters, and kidneys were removed *en masse*. The brain also was examined but nothing abnormal was found.

Detailed description of the genito-urinary organs.—The right kidney was normal in size and appearance; on section it presented no abnormality. The right ureter was normal and measured two and a half inches in length. The ovaries and Fallopian tubes, which were lying on the dorsal abdominal wall, were attached to the perinephritic tissue at the lower end of the kidneys. The left kidney was slightly larger than the right. Scattered over its surface at the upper end were a few small, tense cysts. Two ureters arose from the hilum (see figure), the lower one being normal, the upper and larger one arising from a largely dilated pelvis, distinct from the pelvis belonging to the lower ureter. On section the upper end of the left kidney was found to be completely occupied by the dilated end of the accessory ureter with the exception of the thinned-out cortex, which measured no more than one-eighth of an inch in thickness. The wall of this dilatation was quite smooth and showed no trace of pyramids nor of the openings of the ducts of Bellini to the naked eye. The accessory ureter and its dilated upper end were filled with a pale yellowish and slightly opalescent fluid. The smaller and lower left ureter opened into the lower end of the kidney in a normal manner. The pelvis was small and had about a dozen pyramids projecting into it. The smaller left ureter measured three inches in length and was therefore slightly longer than its fellow of the opposite side. Its diameter was approximately the same as that of the right ureter. The accessory and upper left ureter, which was extremely tortuous, measured six and a quarter inches in length and seven-twelfths of an inch in diameter when flattened out. Where it passed through the bladder wall it was much constricted. It entered the bladder below the opening of the smaller left ureter which opened at the upper limit of the wall of what was apparently a collapsed cyst formed by the lower end of the accessory ureter. The bladder was slightly larger than normal and at the fundus presented no obvious abnormality except that the mucous membrane had a few hæmorrhagic spots upon its surface. Projecting from the left side of the region of the trigone was a pink, thin-walled, pear-shaped, and collapsed cyst, the apex of which passed out through the urethra and probably terminated originally at the vulva in the cystic swelling described above. A fine probe could be passed with difficulty from the interior of the cyst through the constricted part of the ureter which lay in the bladder wall into the dilated accessory ureter above. The smaller left ureter opened at the upper limit of the cyst wall close to its origin from the bladder wall and very near to that margin which was nearest to the middle line of the body. The opening of the right ureter was situated on the posterior bladder wall on a level with the upper border of the cyst and slightly to the right of it. The urethra was dilated but was otherwise normal. The uterus was normal. The ovaries and Fallopian tubes were normal except as regards their position and attachments on the posterior abdominal wall. The vagina and the labia minora and majora were all normal. Microscopic examination of part of the cyst wall showed normal transitional epithelium on its vesical surface and very much thinned and flattened epithelium of the same character on its ureteric surface. Between these two layers of epithelium was some very vascular connective tissue which did not appear to contain any muscle fibres.

Remarks.—In the light of the necropsy it seems probable that this was a case of a dilated accessory ureter either with a blind cystic ending in the bladder wall or with ballooning of its lower end due to congenital narrowing of its orifice. Which of the two it really was it does not seem possible to say now. The treatment pursued in this particular case was dictated by the marked and progressive decrease in size of the protruded swelling and by the total absence of any morbid signs or symptoms exhibited by the child with the exception of the protrusion. Had the condition of the accessory left ureter been ascertained before death, doubtless it would have been better to have made a free communication between the bladder and the cyst, but even as it was the cyst apparently collapsed and the ureter did not, so that probably that treatment would have failed also. It is noteworthy that the thin-walled, pearl-grey appearance of the swelling, which is said to be present often in the case of these so called ureteric cysts, was entirely absent in this case.

MICROSCOPICAL AND CHEMICAL OBSERVATIONS ON A CASE OF SCLEREMA NEONATORUM.¹

By GEORGE CARPENTER, M.D. LOND., M.R.C.P. LOND.,
PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN AND
MEMBRE CORRESPONDANT DE LA SOCIÉTÉ DE PÉDIATRIE
DE PARIS;

AND

SHEFFIELD NEAVE, B.A. OXON., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN.

THIS disease is not often met with, and less often in England than on the continent. Its favourite localities appear to be in Italy and France. It has been confounded in text-books with oedema neonatorum but it is quite distinct and there is no difficulty in diagnosing between the two. There are nevertheless two disorders, differing at any rate in degree, which both go under this name. The first, by far the commoner in this country, attacks otherwise healthy children of normal term at birth and is practically confined to the skin and the subjacent structures, usually ending in recovery at about six months; while the second, which is more usually found on the continent, attacks weaklings often of premature birth, and is a severe malady with serious constitutional symptoms of the alimentary and respiratory systems as well as of the kidney and is very fatal.² The case about to be described is of the first-mentioned order.

The patient was admitted to hospital on Dec. 30th, 1905, being six weeks old, well nourished, with normal temperature, and in fact normal in every way except for the induration of the skin on the posterior aspect of the body. The skin so affected was of a pink, purplish appearance and of a less even outline than usual, having some well-marked dimples and rounded but slight eminences. On applying pressure with the finger and then removing it no pitting occurred, but the colour faded to white and slowly returned as the effect of the finger pressure passed off. When the skin was pinched up between the finger and thumb the underlying tissue being closely adherent appeared when doubled together to keep the fingers more than one inch apart and gave a sensation as if a layer of indiarubber were adherent to the under surface of the skin. This kind of induration extended all over the back and buttocks, the back of the neck and lower part of the back of the scalp, the back of the arms and deltoid regions, and the back of the thighs. In the last-mentioned region it tapered to a point just above the back of the knee in a very characteristic way. The edges of the indurated areas terminated by gradually thinning. Later these signs extended slowly and to a less degree to the angles of the jaws, the sides of the neck, down the arms nearly to the wrist, and there were islets formed all over the abdomen and chest. Pain was never an accompaniment of these indurations. During the five months the child has been under observation, although the above extensions took place, these signs have cleared up irregularly but continuously. At the time of writing a small triangular patch of induration exists between the shoulders with the apex downwards on the spine, but it is not nearly so thick or hard as in the first place. There are a small patch on the right buttock and an islet on the right cheek just below the superior maxilla. The glands are somewhat enlarged and shotty in the posterior triangle of the neck and in the groin and the spleen reaches one finger's breadth below the ribs. Throughout there was nothing distinctive taking place in respect of the temperature. A blood count was made but gave nothing very definite—viz., polymorphs, 34; lymphocytes, 57.5; large mononuclears, 0.6; myelocytes, 0.5; and eosinophiles, 2; total, 100; erythrocytes, 4,212,000; and leucocytes, 22,500. The child has during her stay in the hospital thrived very satisfactorily and the skin has cleared up as described under massage, together with, first, thyroid and then thymus extract given internally. The thyroid was first given for a month when some improvement was made. Thymus was then given, beginning with a small dose and being raised to

30 grains per diem, though subsequently reduced to half that amount. During this last treatment progress appeared to be much hastened.

A small piece of skin and subcutaneous tissue down to the muscle was excised by Mr. J. P. Lockhart Mummery from the back of the thigh for microscopical examination. Macroscopically, the fat and superficial fascia appeared to be perhaps thicker than usual but only slightly. The fat, however, was certainly whiter and in larger globules than usual and was much harder to the touch. Nothing further abnormal was, however, detected under the microscope, a control examination being made at the same time of a similar specimen of healthy skin from another child of the same age. The serous infiltration and increase of connective tissue mentioned in some cases were certainly absent and in this way this case agrees with that of Northrup mentioned by Holt.

The fat was submitted to Professor J. Addyman Gardner, M.A., F.I.C., for examination. He reported as follows:—

I am afraid my investigations do not throw much light on the case. There were two difficulties which it was impossible to get over: (1) the small quantity of the sample, and (2) the fact that it was probably somewhat altered by the prolonged soaking in the formalin fluid. The dry specimen contained only 68 per cent. of fat, the rest being ordinary tissue matter, as far as could be determined in the dried residue after extraction, and this appears to agree with your microscopical report. The saponification equivalent was 205. The specimen also contained unsaturated fat—e.g., olein—but it was too small to permit of a quantitative estimation. The values usually given for the saponification equivalents of the various pure fats are: tripalmitin 209, tristearin 189, triolein 197, horse fat 190.4. One might conclude from this that the specimen was particularly rich in palmitin. In the hope of throwing some light on the matter I examined the saponification equivalents of specimens of human fat cut from various parts of the body but they showed very considerable variation.

I thought at first that the specimen of fat and the acids from it seemed more solid than is usual in human fat, but my examination of the specimen mentioned scarcely bears this out.

On the whole, I am inclined to doubt whether the fat in the sample was in any way abnormal and think that the cause of the trouble must be sought in the associated matter.

It is thus obvious that the pathology of the disease is very obscure and it is hoped to call attention to the malady by the publication of this case, so that the work done here, although so negative, may be of some use to others as a starting-point for further investigation when new cases are obtainable.

A CASE OF ACTINOMYCOSIS.

PRIMARY ABSCESS OF THE LEFT LUNG EXHIBITING SPONTANEOUS CURE; METASTATIC MANIFESTATION IN THE PELVIS DECLARING ITSELF AFTER A YEAR'S LATENCY WITH ABSCESS FORMATION AND SLOW SPONTANEOUS CURE.

By EDGAR TREVITHICK, M.D. CANTAB.

THIS illness occurred in a boy, aged 16 years, and has afforded a good example of a prolonged encounter between a living parasitic fungus on the one hand and human tissues on the other. If, as in this case, there now seems good reason to hope the tissues have ultimately succeeded in permanently stamping out the invasion they alone must be credited with the honours of the victory, for I have not been able to satisfy myself that any of the numerous artificial remedies that have been used have rendered any real assistance towards the patient's recovery.

There have been many points of interest observable in the course of this case of actinomycosis. It has illustrated in a marked degree the beneficent capabilities of rapid deposition of solid inflammatory exudation and has demonstrated with what great rapidity such exudation can be re-absorbed when its presence is no longer of service. It exemplifies the fact that a parasite may exist somewhere in the body for many months without showing any obvious signs of its whereabouts and that it may, after long periods of latency, declare its presence by stimulating violent and extensive tissue resentment.

One is tempted to suspect that during the long interval that elapsed in this case between the obsolescence of the original pulmonary lesion and the subsequent breaking-out of the secondary manifestation in the pelvis, obscure internal evolutions of some sort may have been taking place without giving rise to any gross manifestations. The condition of the patient's blood rather favoured such a view. For at the very outset of the second attack there was already

¹ The case was exhibited at the Society for the Study of Disease in Children on Jan. 19th, 1906, and the observations herein recorded were conducted subsequently.

² Dr. A. M. Gray, the resident medical officer, has searched the records of the North-Eastern Hospital for Children for the past ten years and could find no mention of a case similar to the one about to be reported during that period of time.

marked leucocytosis and in addition great excess of extra-cellular bodies. And it is interesting to wonder along what path the parasite passed in its slow transit from one part of the body to another. The rapid fluctuations of body weight exhibited by the patient during the illness were very striking and the rapid spontaneous cure of the faecal fistula that resulted in the course of the contest is also of interest.

History of the pulmonary attack.—When first seen on Oct. 19th, 1903, the boy was very wasted, had marked hectic flush, and complained of shortness of breath. He had been employed in "carrying milk from the farm to the village" and had "caught cold," he thought, three months previously. Even since that time he had been getting thinner and losing strength and just recently he had suffered from troublesome dry cough, loss of appetite, and diarrhoea. There had been no expectation but his friends "had noticed a very curious odour about his breath." On examination I found evidence of extensive consolidation in the lower lobe of the left lung and I, too, was struck by the curious odour of the breath. On Oct. 26th the patient began to cough up very large quantities of offensive pus, the odour of which resembled that previously remarked in the breath. With the onset of this copious expectoration the general condition began rapidly to improve. A few days later the physical signs indicated the existence of a cavity about the centre of the lower lobe of the left lung, surrounded by a broad zone of consolidation. By Nov. 13th the cough and expectoration were very much less and the latter was no longer offensive. The boy went to a convalescent home on Nov. 30th, weighing 7 stones 7 pounds, having gained 21 pounds in body weight in 27 days. And later he went back to his own home in the country as "cured" and was written down as having suffered from "abscess of left lung."

It must be confessed that at this stage of the illness no diagnosis of actinomycosis was made. The characteristic yellow bodies which were so plentiful in the discharges from the subsequent pelvic lesions were not noticed in the sputum. They were not, indeed, either thought of or sought for. But certain observations that were written down at the time, taken together with the study of the subsequent course of the case, make it, I think, certain that this pulmonary abscess was in reality caused by the same organism as later asserted itself in another part of the body.

A note written on Oct. 24th, 1903, describes the sputum as follows: "Very offensive, with singular odour. Shreddy, making films that stain badly and seem to contain fatty material. No tubercle bacilli, but swarming with very fine hair-like streptococci showing curious tendency to interlace into tangles." This was a clumsy description but a sketch I made at the time showing the organism, together with my recollection, makes me certain that the "very fine hair-like streptococcus" was in reality derived from actinomyces and makes it probable that the yellow characteristic bodies, although overlooked, may yet have been present. It is not improbable that ordinary clinical observation is easily capable of overlooking their presence in sputum; indeed, this case has led me to reflect about certain other cases of "pneumonia" that have from time to time presented puzzling features and yielded puzzling sputa. I suspect that even in hospital practice the term "pneumonia" as sometimes used is more convenient than scientific.

History of the secondary attack.—After about a year's "perfectly good health" the boy came back complaining of pain in his left flank and exhibiting a very hard craggy lump firmly attached to the brim of the pelvis. From Oct. 26th, 1904, to Sept. 28th, 1905, he was ill in bed and during this year he passed through many vicissitudes of illness, being more than once seemingly at death's door. The body weight in September, 1904, had been 8 stones 2 pounds and this gradually decreased until on April 3rd, 1905, it was 6 stones 4 pounds. At this latter date there was very extensive involvement of the lower part of the abdomen. The infested areas were obstinately and lavishly circumscribed by very extensive barriers of solid inflammatory exudation, which eventually reached as high as the level of the umbilicus. This abdominal contest was accompanied by irregular and sometimes very high pyrexia and led to the formation of two separate intra-peritoneal abscesses, one of which eventually communicated with the large intestine. There was considerable enlargement of the spleen and the patient's troubles were much aggravated by pressure on nerves and bedsores. About this time it seemed as if recovery was very unlikely. In the end, however, the tissues, as

had been the case in the original pulmonary attack, were victorious. On Oct. 2nd, 1905, the body weight had risen to 8 stones 12 pounds. The faecal fistula had healed spontaneously. The discharge from the two abdominal issues was very greatly reduced and the intra-abdominal buttresses of seemingly solid tissue had all but disappeared. Since Nov. 1st, 1905, the patient had been at work as a baker and in June, 1906, when I saw him, he reported himself and looked in excellent health.

On the subject of treatment I have nothing much to say. The initial manifestation in the lung subsided and healed spontaneously. During the long activity of the subsequent pelvic manifestations many lines of treatment were tried. I was induced to give a long trial to the x rays. I thought their application increased the vascularity of the tissue in the neighbourhood of the issues. Iodide of potassium seemed to me to have no effect.

Bacteriological considerations.—The yellowish bodies characteristic of actinomycosis were abundant for several months in the purulent discharge obtained from the intra-abdominal lesions. They were examined by several pathologists who all agreed as to their nature. When one of these bodies, after having been cleansed in sterile salt solution, was incubated in broth a very copious yellowish deposit always formed round it at the bottom of the tube in the course of a few days. And microscopically this deposit, in addition to containing masses of finely divided parts, was always rich in elongated hair-like filaments. Three different observers failed to obtain cultures from it on the surface of solid media. It was injected subcutaneously in rabbits but failed to produce actinomycosis.

I took a good deal of interest in examining the discharges from these lesions. There are observable among the pus cells irregularly shaped interlacings of very delicate filaments, containing in their interstices aggregations of minute bodies irregularly rectangular in shape. There were also present considerable numbers of the characteristic yellow bodies already mentioned as being visible to the naked eye. These latter seemed on examination to consist of a yellowish amorphous central core, an intermediate interlacement of filaments and a peripheral dressing of club-like bodies. It does not seem very difficult, I think, to imagine the filamentous interlacings blossoming out into full-blown characteristic bodies. This imagination was strengthened by observing sections of young colonies of *aspergillus glaucus* and noting the relationship between the strongly eosinophile and charmingly graceful fruit-heads and the basophile mycelium from which they spring.
